Several recent studies examined the role of ACE2 in SARS-CoV-2 binding and cellular infection, and its relationship to experimental and natural infections in different species (30, 41–46). Our study design differs substantially from those studies in several aspects: 1) we analyzed a larger number of primates, carnivores, rodents, cetartiodactyls and other mammalian orders, and an extensive phylogenetic sampling of fishes, birds, amphibians and reptiles; 2) we analyzed the full complement of S-binding residues across the ACE2 binding site, which was based on a consensus set from two independent studies (13, 21); 3) we used different methodologies to assess ACE2 binding capacity for SARS-CoV-2 S; and, 4) our study tested for selection and accelerated evolution across the entire ACE2 protein. While our results are strongly consistent with the results and conclusions of Melin and colleagues (44) on the predicted susceptibility of primates to SARS-CoV-2, particularly Old World primates, our work made predictions for a larger number of primates (N=39 vs N=27), bats (N=37 vs N=7), other mammals (N=176 vs N=5) and other vertebrates (N=158 vs N=0). When ACE2 from species in our study were compared with results of other studies there were many consistencies, such as for rodents, but some predictions that differ, such as the relatively high risk described for SARS-CoV-2 binding in pangolin and horse (45), civet (46), *Rhinolophus sinicus* bats (46) and turtles (45). In one recent study, binding affinity of soluble ACE2 for the SARS-CoV-2 S RBD was analyzed by saturation mutagenesis (26). Results obtained at each ACE2 binding residue were generally consistent with ours, particularly in the binding hotspot region of ACE2 residues 353-357. Importantly, as compared with other studies, our results greatly expanded the potential number of intermediate hosts and identified many more threatened species that could be infected by SARS-CoV-2 via their ACE2 receptors.

Evolution of *ACE2*. Variation of *ACE2* in the human population is rare (17). We examined a large set of *ACE2* variants for their potential differences in binding to SARS-CoV-2 S and their relationship to selected and accelerated sites. We found rare variants that would result in missense mutations in 7 out of the 25 binding residues (Dataset S2). Some of those (e.g. E35K with an AF of 0.00001636) could reduce the virus binding affinity, thus potentially lowering the susceptibility to the virus in a very small fraction of

the population. The analysis suggests that some variants (e.g. D38E) might not affect the binding while others (e.g. S19P) have uncertain effects. Further studies are needed to confirm and correctly address recent discoveries (18, 27, 28) and the data presented here, investigating the possible effect of these rare variants in specific populations.

When exploring patterns of codon evolution in ACE2, we found that a number of sites are evolving at different rates in the different lineages represented in our 410-species vertebrate alignment. Multiple ACE2 RBD residues important for the binding of SARS-CoV-2 are evolving rapidly across mammals, with two (Q24 and H34) under positive selection (Fig. 3, Fig. S5). Relative to other lineages analyzed, Chiroptera has a greater proportion of accelerated versus conserved residues, particularly at the SARS-CoV-2 S RBD, suggesting the possibility of selective forces on these codons in Chiroptera driven by their interactions with SARS-CoV-2-like viruses (Dataset S4.12, Fig. S8). Indeed, distinct signatures of positive selection found in bats and in the SARS-CoV S protein support this hypothesis that bats are evolving to tolerate SARS-CoV-2-like viruses.

Relationship of the ACE2 binding score to known infectivity of SARS-CoV-2. Data on susceptibility of wild animals to SARS-CoV-2 is still very limited. It has been reported that a captive Malayan tiger was infected by SARS-CoV-2 (9) and that domestic cats, ferrets (47), rhesus macaques (48) and Syrian golden hamsters (49) are susceptible to experimental infection by SARS-CoV-2. These results agree with our predictions of ACE2 binding ability to SARS-CoV-2 S (Fig. 1, Dataset S1); 4/5 five species with demonstrated susceptibility to SARS-CoV-2 score *very high* (Rhesus macaque) or *medium* (domestic cat, tiger and Golden hamster). The only inconsistency was observed for ferrets, which had a *low* ACE2 binding score. This inconsistency could be related to the high infectivity dose used for experimental infection that likely does not correspond to virus exposure in nature. Dogs have low susceptibility to SARS-CoV-2 under experimental conditions (47), and score *low* for binding of their ACE2 to SARS-CoV-2 S. However, kidney cell lines derived from dog showed ACE2-dependent SARS-CoV-2 S entry, suggesting that *in vitro* experiments may be overestimating true infectivity potential (39, 50). Pigs (*low*), ducks (*very low*) and chickens (*very low*) were similarly exposed to SARS-CoV-2 and showed no susceptibility (47), providing further support of our methodology. A recent publication reporting that SARS-CoV-2 could use pig, masked palm civet and Chinese rufous horseshoe bat ACE2 expressed in HeLa cells were inconsistent with our predictions, while data for mouse was in agreement (1). Indeed, while mouse ACE2 scored *very low* in our analysis, pig and Chinese rufous horseshoe bat score *low*, while the masked palm civet scored *very low*. As for the ferret, high-level exposure to the virus *in vitro* could potentially result in infection via low affinity interactions with ACE2. Another possibility is that other cellular machinery

present in the human HeLa cells is facilitating the infection, and that infectivity does not relate directly to ACE2 differences in these species. Confirmation of *in vitro* and *in vivo* susceptibility of these species under physiological conditions and with proper controls is clearly necessary. In addition, the expression of ACE2 varies across animal age, cell types, tissues and species (51, 52), which may lead to discrepancies between SARS-CoV-2 susceptibility gleaned from experimental infections or laboratory experiments and predictions made from the ACE2-based binding score.

Mammals with high predicted risk of SARS-CoV-2 infection. Of the 19 catarrhine primates analyzed, 18/19 scored *very high* for binding of their ACE2 to SARS-CoV-2 S and one scored *high* (the Angola colobus); the 18 species scoring *very high* had 25/25 identical binding residues to human ACE2, including rhesus macaques (*Macaca mulatta*), which are known to be infected by SARS-CoV-2 and develop COVID-19-like clinical symptoms (3, 48). Our analysis predicts that all Old World primates are susceptible to infection by SARS-CoV-2 via their ACE2 receptors. Thus, many of the 21 primate species native to China could be a potential reservoir for SARS-CoV-2. The remaining primate species were scored as *high* or *medium*, with only the Gray mouse lemur and the Philippine tarsier scoring as *low*.

We were surprised to find that all three species of Cervid deer and 12/14 cetacean species have *high* scores for binding of their ACE2s to SARS-CoV-2 S. There are 18 species of Cervid deer found in China. Therefore, Cervid deer cannot be ruled out as an intermediate host for SARS-CoV-2. While coronavirus sequences have been found in white tailed deer (53) and gammacoronaviruses have been found in beluga whales (54, 55) and bottlenose dolphins (56) and are associated with respiratory diseases, the cellular receptor used by these viruses is not known.

Other artiodactyls. A relatively large fraction (21/30) of artiodactyl mammals were classified with *medium* score for ACE2 binding to SARS-CoV-2 S. These include many species that are commonly found in Hubei Province and around the world, such as domesticated cattle, sheep and goats, as well as many species commonly found in zoos and wildlife parks (e.g., Masai giraffe, okapi, hippopotamus, water buffalo, scimitar horned oryx, and Dama gazelle). Although cattle MDBK cells were shown in one study to be resistant to SARS-CoV-2 *in vitro* (50), we propose immediate surveillance of common artiodactyl species for SARS-CoV-2 and studies of cellular infectivity, given our predictions. If ruminant artiodactyls can serve as a reservoir for SARS-CoV-2, it would have significant epidemiological implications as well as implications for food production and wildlife management (see below). It is noteworthy that camels and pigs, known for their ability to be infected by coronaviruses (35), both score *low* in our analysis. These

data are consistent with results (discussed above) indicating that pigs cannot be infected with SARS-CoV-2 both *in vivo* (47) and *in vitro* (50).

Rodents. Among the rodents, 7/46 species score *high* for ACE2 binding to SARS-CoV-2 S, with the remaining 11, 10 and 18 scoring *medium*, *low* or *very low*, respectively. Brown rats *(Rattus norvegicus*) and the house mouse (*Mus musculus*), scored *very low*, consistent with infectivity studies (1, 50). Given that wild rodent species likely come in contact with bats as well as with other predicted high risk species, we urge surveillance of *high* and *medium* binding likelihood rodents for the presence of SARS-CoV-2.

Bats and other species of interest. Chiroptera (bats) represent a clade of mammals that are of high interest in COVID-19 research because several bat species are known to harbor coronaviruses, including those most closely related to the betacoronavirus SARS-CoV-2 (1). We analyzed ACE2 from 37 bat species of which 8 and 29 scored *low* and *very low*, respectively. These results were unexpected because the three *Rhinolophus* spp. including the Chinese rufous horseshoe bat are major suspects in the transmission of SARS-CoV-2, or a closely related virus, to humans (1). Globally, bats have been shown to harbour the highest diversity of betacoronaviruses in mammals tested (35) and show little pathology carrying these viruses (57). We found evidence for accelerated evolution at six RBD binding domain residues within the bat lineage, which is more than in any other lineage tested. Bats also had far more sites showing evidence of positive selection, including four binding domain residues, compared to other mammalian orders. This suggests that the diversity observed in bat ACE2 sequences may be driven by selective pressure from coronaviruses. Our results suggest that SARS-CoV-2 is not likely to use the ACE2 receptor in bats, which challenges a recent study showing that SARS-CoV-2 can infect HeLa cells expressing *Rhinolophus sinicus* ACE2 (1). If bats can be infected with SARS-CoV-2, the virus likely uses a different receptor. For example, the MERS-CoV, a betacoronavirus, uses CD26/DPP4 (16) while the porcine transmissible enteritis virus, an alphacoronavirus uses aminopeptidase N (ANPEP) (58). As detailed above, further *in vitro* and *in vivo* infectivity studies are required to fully understand the mode of transmission of susceptibility of bats to SARS-CoV-2.

Carnivores. Recent reports of a Malayan tiger and a domestic cat infected by SARS-CoV-2 suggest that the virus can be transmitted to other felids (9, 47). Our results are consistent with these studies; 9/9 felids we analyzed scored *medium* for ACE2 binding of SARS-CoV-2 S. However, the masked palm civet (*Paguma larvata*), a member of the Viverridae family that is related to but distinct from Felidae, scored as *very low*. These results are inconsistent with transfection studies using civet ACE2 receptors expressed in HeLa cells (1), although these experiments have limitations as discussed above. While

carnivores closely related to dogs (dingos, wolves and foxes) all scored *low*, experimental data supporting infection in dogs were inconsistent (47, 50, 59) so no conclusions can be drawn.

Pangolins. Considerable controversy surrounds reports that pangolins can serve as an intermediate host for SARS-CoV-2. Pangolins were proposed as a possible intermediate host (22) and have been shown to harbor related coronaviruses. In our study, ACE2 of Chinese pangolin (*Manis pentadactyla*), Sunda pangolin (*Manis javanica*), and white bellied pangolin (*Phataginus tricuspis*) had *low* or *very low* binding score for SARS-CoV-2 S. Neither experimental infection nor *in vitro* infection with SARS-CoV-2 has been reported for pangolins. As for ferrets and bats, if SARS-CoV-2 infects pangolins it may be using a receptor other than ACE2, based on our analysis.

Other vertebrates. Our analysis of 29 orders of fishes, 29 orders of birds, 3 orders of reptiles and 2 orders of amphibians predicts that the ACE2 proteins of species within these vertebrate classes are not likely to bind SARS-CoV-2 S. Thus, vertebrate classes other than mammals are not likely to be an intermediate host or reservoir for the virus, despite predictions reported in a recent study (45), unless SARS-CoV-2 can use another receptor for infection. With many different non-mammal vertebrates sold in the seafood and wildlife markets of Asia and elsewhere, it is still important to determine if SARS-CoV-2 can be found in non-mammalian vertebrates.

Relevance to Threatened Species. Among the 103 species that scored *very high*, *high* and *medium* for ACE2 SARS-CoV-2 S RBD binding, 41 (40%) are classified in one of three 'Threatened' categories (*Vulnerable*, *Endangered*, and *Critically Endangered*) on the IUCN Red List of Threatened Species, five are classified as *Near Threatened*, and two species are classified as *Extinct in the Wild* (Dataset S1)(60). This represents only a small fraction of the threatened species potentially susceptible to SARS-CoV-2. For example, all 20 catarrhine primate species in our analysis, representing three families (Cercopithecidae, Hylobatidae, and Hominidae) scored *very high*, suggesting that all 185 species of catarrhine primates, most of which are classified Threatened (62), are potentially susceptible to SARS-CoV-2. Similarly, all three species of deer, representatives of a family of ~92 species (Cervidae), scored as *high* risk, as did species representing Cetacea (baleen and toothed whales), and both groups contain a number of threatened species. Toothed whales have potential for viral outbreaks and have lost function of a gene key to the antiviral response in other mammalian lineages (61). If they are susceptible to SARS-CoV-2 , human-to-animal transmission could pose a risk through sewage outfall (62) and contaminated refuse from cities, commercial vessels and cruise liners (63). In contrast, some threatened species scored *low* or *very low*, such as the giant panda (*low*), potentially positive news for these at risk populations.

Our results have practical implications for populations of threatened species in the wild and those under human care (including those in zoos). Established guidelines for minimizing potential human to animal transmission should be implemented and strictly followed. Guidelines for field researchers working on great apes established by the IUCN have been in place since 2015 in response to previous human disease outbreaks (64) and have received renewed attention because of SARS-CoV-2 (64–66). For zoos, guidelines in response to SARS-CoV-2 have been distributed by several Taxon Advisory Groups of the North American Association of Zoos and Aquariums (AZA), the American Association of Zoo Veterinarians (AAZV), and the European Association of Zoo and Wildlife Veterinarians (EAZWV), and these organizations are actively monitoring and updating knowledge of species in human care considered to be potentially sensitive to infection (67, 68). Although *in silico* studies suggest potential susceptibility of diverse species, verification of infection potential is warranted, using cell cultures, stem cells, organoids, and other methods that do not require direct animal infection studies. Zoos and other facilities that maintain living animal collections are in a position to provide such samples for generating crucial research resources by banking tissues, and cryobanking viable cell cultures in support of these efforts.

Animal models for COVID-19. A variety of animal models have been developed for studying SARS and MERS coronavirus infections (69). Presently, there is a tremendous need for animal models for studying SARS-CoV-2 infection and pathogenesis, as the only species currently known to be infected and show similar symptoms of COVID-19 is rhesus macaque. Non-human primate models have proven to be highly valuable for other infectious diseases, but are expensive to maintain and numbers of experimental animals are limited. Our results provide an extended list of potential species that might be useful as animal models for SARS-CoV-2 infection and pathogenesis, including Chinese hamster and Syrian/Golden hamster (49), and large animals maintained for biomedical and agricultural research (e.g., domesticated sheep and cattle).

Conclusions. We predict that species scored as *very high* and *high* for SARS-CoV-2 S binding to ACE2 will have a high probability of becoming infected by the virus. We also predict that many species having a *medium* score have some risk of infection, and species scored as *very low* and *low* are unlikely to be infected by SARS-CoV-2 via the ACE2 receptor. Importantly, our predictions are based solely on *in silico* analyses and must be confirmed by direct experimental data. Until such time, other than for species in which SARS-CoV-2 infection has been demonstrated to occur using ACE2, we urge caution not to over-interpret the predictions made in the present study. This is especially important with regards to species, endangered or otherwise, in human care. While species ranked *high* or *medium* may be

susceptible to infection based on the features of their ACE2 residues, pathological outcomes may be very different among species depending on other mechanisms that could affect virus replication and spread to target cells, tissues, and organs within the host. Furthermore, we cannot exclude the possibility that infection in any species occurs via another cellular receptor, as has been shown for other betacoronaviruses. Nonetheless, our predictions provide a useful starting point for selection of appropriate animal models for COVID-19 research and for identification of species that may be at risk for human-to-animal or animal-to-animal transmissions by SARS-CoV-2. The approach we used for ACE2 can be extended to other cellular proteins known to be involved in coronavirus infection and immunity to better understand infection, transmission, inflammatory responses and disease progression.

Materials and Methods

Angiotensin I converting enzyme 2 (ACE2) coding and protein sequences. All human ACE2 orthologs for vertebrate species, and their respective coding sequences, were retrieved from NCBI Protein (March 20, 2020) (70). ACE2 coding DNA sequences were extracted from available or recently sequenced unpublished genome assemblies for 123 other mammalian species, with the help of genome alignments and the human or within-family ACE2 orthologs. The protein sequences were predicted using AUGUSTUS v3.3.2 (71) or CESAR v2.0 (72) and the translated protein sequences were checked against the human ACE2 orthologue. ACE2 gene predictions were inspected and manually curated if necessary. For four bat species (*Micronycteris hirsuta*, *Mormoops blainvillei*, *Tadarida brasiliensis* and *Pteronotus parnellii*) the ACE2 coding region was split into two scaffolds which were merged, and for *Eonycteris spelaea* a putative 1bp frameshift base error was corrected. Eighty ACE2 predictions were obtained from the Zoonomia project, 19 from the Hiller Lab, 12 from the Koepfli lab, 8 from the Lewin lab and 4 from the Zhou lab. The source, and accession numbers for the genomes or proteins retrieved from NCBI are listed in Dataset S1. The final set of ACE2 sequences comprises 410 vertebrate species. To assure alignment robustness, the full set of coding and protein sequences were aligned independently using Clustal Omega (73), MUSCLE (74) and COBALT (75) all with default parameters. All resulting protein alignments were identical. Clustal Omega alignments were used in the subsequent analysis. Each amino acid replacement present in our dataset was classified as neutral, semi-conservative and non-conservative as in Clustal Omega.

Identification of ACE2 residues involved in binding to SARS-CoV-2 S protein. We identified 22 ACE2 protein residues that were previously reported to be critical for the effective binding of ACE2 RBD and

SARS-CoV-2 S (13, 21). These residues include S19, Q24, T27, F28, D30, K31, H34, E35, E37, D38, Y41, Q42, L45, L79, M82, Y83, N330, K353, G354, D355, R357, and R393. All these residues were identified from the co-crystallization and structural determination of SARS-CoV-2 S and ACE2 RBD (13, 21). The known human ACE2 RBD glycosylation sites N53, N90 and N322 were also included in the analyzed residue set (11).

ACE2 and SARS-CoV-2 binding ability prediction. Based on the known interactions of ACE2 and SARS-CoV-2 residues, we developed a set of rules for predicting the likelihood of the SARS-CoV-2 S binding to ACE2. Each species was classified in one of five categories: *very high*, *high*, *medium*, *low* or *very low* likelihood of binding SARS-CoV-2 S. Species in the *very high* category have at least 23/25 critical residues identical to the human; have K353, K31, E35, M82, N53, N90 and N322; do not have N79; and have only conservative substitutions among the non-identical 2/25 residues. Species in the *high* group have at least 20/25 residues identical to the human; have K353; have only conservative substitutions at K31 and E35; do not have N79; and can only have one non-conservative substitution among the 5/25 non-identical residues. Species scoring *medium* have at least 20/25 residues identical to the human; can only have conservative substitutions at K353, K31, and E35; and can have up to two non-conservative substitutions in the 5/25 non-identical residues. Species in the *low* category have at least 18/25 residues identical to the human; can only have conservative substitutions at K353; can have up to three non-conservative substitutions on the remaining 7/25 non-identical residues. Lastly, species in the *very low* group have less than 18/25 residues identical to the human or have at least four non-conservative substitutions in the non-identical residues.

Protein structure analysis. We applied an orthogonal approach to assess the likelihood of binding of a sampling of species that were predicted to bind SARS-CoV-2 across the categories of *high*, *medium*, *low* or *very low* likelihood of binding. ACE2 amino acid sequences from 28 species were extracted from the multiway alignment and loaded into SWISS-MODEL (25) in order to generate homology derived models. The output files were aligned to the crystal structure 6MOJ (13) in order to assess the overall similarities to human ACE2. We used two recently solved crystal structures of the complex for ACE2 and SARS-CoV-2 S RBD, 6MOJ (13) and 6VW1 (21) as ground truth for the human ACE2/SARS-CoV-2 S interaction. In the program CHIMERA (76), we utilized the rotamer function to model each individual variant that species exhibit separately, and chose the rotamer with the least number of clashes, retaining the most initial hydrogen bonds and containing the highest probability of formation as calculated by CHIMERA from the Dunbrack 2010 backbone-dependent rotamer library (77). The rotamer was then evaluated in the context of its structural environment and assigned a score based on likelihood of interface disruption.

Neutral (N) was assigned if the residue maintained a similar environment as the original residue, and was predicted to maintain or in some cases increase affinity. Weakened (W) was assigned if hydrophobic contacts were lost and contacts that appear disruptive are introduced that are not technically clashes. Unfavorable (U) was assigned if clashes are introduced and/or a hydrogen bond is broken. Additional structural visualizations were generated in Pymol (78).

Human variants analysis. All variants at the 25 residues critical for effective SARS-CoV-2-ACE2 binding (11, 21, 79) were compiled from from dbSNP (31), 1KGP (32), Topmed (33), UK10K (34) and CHINAMAP (28). Specific population frequencies were obtained from gnomAD v.2.1.1 (17).

Phylogenetic reconstruction of the vertebrate *ACE2* species tree. The multiple sequence alignment of 410 ACE2 orthologous protein sequences from mammals, birds, fishes, reptiles and amphibians was used to generate a gene tree using the maximum likelihood method of reconstruction, as implemented in IQTREE (80). The best fit model of sequence evolution was determined using ModelFinder (81) and used to generate the species phylogeny. A total of 1000 bootstrap replicates were used to determine node support using UFBoot (82).

Identifying sites undergoing positive selection. Signatures of site-specific positive selection in the *ACE2* receptor were explored using CODEML, part of the Phylogenetic Analysis using Maximum Likelihood (PAML, (83)) suite of software. Given CODEML's computational complexity, a smaller subset of mammalian taxa (N=64, Dataset S1), which included species from all prediction categories mentioned above, was used for selection analyses. To calculate likelihood-derived dN/dS rates (ω), CODEML utilises both a species tree and a codon alignment. The species tree for all 64 taxa was calculated using IQTREE (80) and the inferred best-fit model of sequence evolution (JTT+F+R4). This gene topology was generally in agreement with the 410 taxa tree, however bats were now sister taxa to Perissodactyla. Therefore all selection analyses were run using both the inferred gene tree, and a modified tree with the position of bats manually modified to reflect the 410 taxa topology. All species trees used were unrooted. A codon alignment of the 64 mammals was generated using pal2nal (84) with protein alignments generated with Clustal Omega (73) and their respective CDS sequences.

Site-models M7 (null model) and M8 (alternative model) were used to identify *ACE2* sites undergoing positive selection in mammals. Both M7 and M8 estimate ω using a beta distribution and 10 rate categories per site with ω<=1 (neutral or purifying selection), but with an additional 11^{th} category allowing ω >1 (positive selection) in M8. A likelihood ratio test (LRT) calculated as $2*(\ln L_{alt} - \ln L_{null})$, comparing the fit of both null and alternative model likelihoods was carried out, with a p-value

calculated assuming a chi-squared distribution. Sites showing evidence of positive selection were identified by a significant (>0.95) Bayes Empirical Bayes (BEB) score, and validated by visual inspection of the protein alignment. To explore order-specific instances of positive selection, separate multiple sequence alignments and gene trees for Chiroptera (N=37), Cetartiodactyla (N=45), Carnivora (N=44), Rodentia (N=46) and Primates (N=39) were also generated and explored using M7 vs. M8 in CODEML.

In addition to site-models, branch-site model A1 (null model) and model A (alternative model) were also implemented targeting various mammalian orders, specifically Chiroptera, Cetartiodactyla, Rodentia and Primates, to identify lineage-specific positive selection in the *ACE2* receptor sequence. Branch-site Model A1 constrains both the target foreground branch (Carnivora, Chiroptera, Cetartiodactyla, Rodentia and Primates) and background branches to $\omega<=1$, while the alternative Model A allows positive selection to occur in the foreground branch. Null and alternative models were compared using LRTs as above, with significant BEB sites identified.

We also looked for positively selected sites in the viral spike protein, using SARS-CoV-2 (MN908947.3), Bat coronavirus RaTg13 (MN996532.1), Bat SARS-like coronavirus isolate Rs4231 (KY417146.1), SARS-related coronavirus strain BtKY72 (KY352407.1), SARS coronavirus Urbani (AY278741.1), SARS coronavirus PC4-227 (AY613950.1), Coronavirus BtRs-BetaCoV/YN2018B (MK211376.1) and the more divergent Bat Hp-betacoronavirus/Zhejiang2013 (NC_025217.1) viral strains. Protein and codon alignments were generated as above, with the viral species tree inferred using full genome alignments of all strains generated with Clustal Omega (73). Site-test models were applied using CODEML, and significant BEB sites identified.

Analysis for departure from neutral evolutionary rate in ACE2 with PHAST. Neutral models were trained on the specified species sets (Dataset S4) using the REV nucleotide substitution model implemented in phyloFit using an expectation maximization algorithm for parameter optimization. The neutral model fit was based on third codon positions to approximate the neutral evolution rate specific to the *ACE2* gene, using a 410-species phylogenetic tree generated by IQTREE as described above and rooted on fishes. The program phyloP was then used to identify codons undergoing accelerated or conserved evolution relative to the neutral model using --features to specify codons, --method LRT --mode CONACC, and --subtree for lineage-specific tests, with p-values thus assigned per codon based on a likelihood ratio test. P-values were corrected for multiple testing using the Benjamini-Hochberg method (36) and sites with a corrected p-value less than 0.05 were considered significant. PhyloFit and phyloP are both part of the PHAST package v1.4 (85, 86).

Acknowledgements

We thank Lawrence Stern for helpful discussions on homology modeling. We thank Pavel Dobrynin, Paul Frandsen, Taylor Hains, Sergei Kliver, and Alice Mouton for extracting and contributing ACE2 sequences from unpublished genomes. We thank Shirley Xue Li and Kate Megquier for help in data compilation. We thank Pierre Comizzoli, Budhan Pukazhenthi, and Nucharin Songasasen for valuable comments that improved the manuscript. This work was supported by the Robert and Rosabel Osborne Endowment (HAL). KLT is the recipient of a Distinguished Professor award from the Swedish Research Council. ECT is funded by an Irish Research Council Laureate Award. KCK is supported by a UCSF Discovery Fellowship and the Gladstone Institutes. GMH is funded by an Ad Astra Fellowship at University College Dublin. EKK, DPG and RS were supported by NIH R01HG008742. The research conducted in this study was coordinated as part of the Genome 10K Consortium, which includes the Bat1K, Zoonomia, the Vertebrate Genomes Project, and the Earth BioGenome Project.

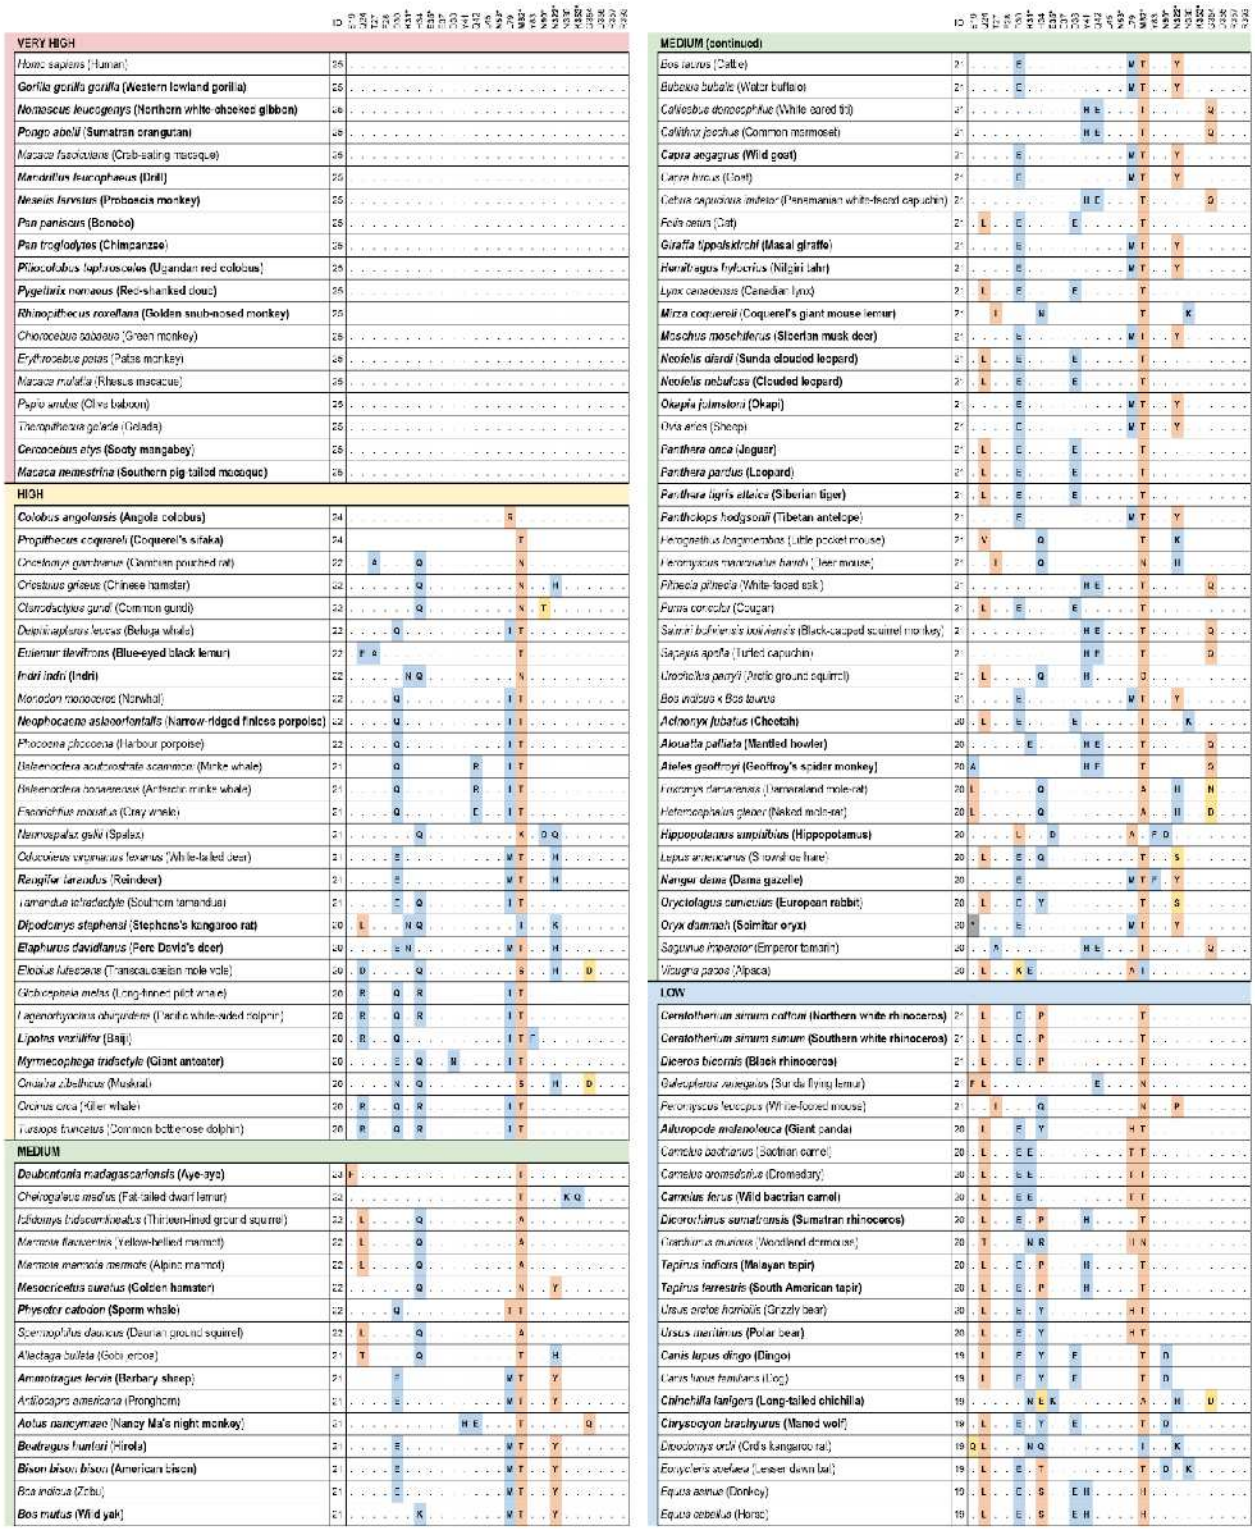
Figures and Tables



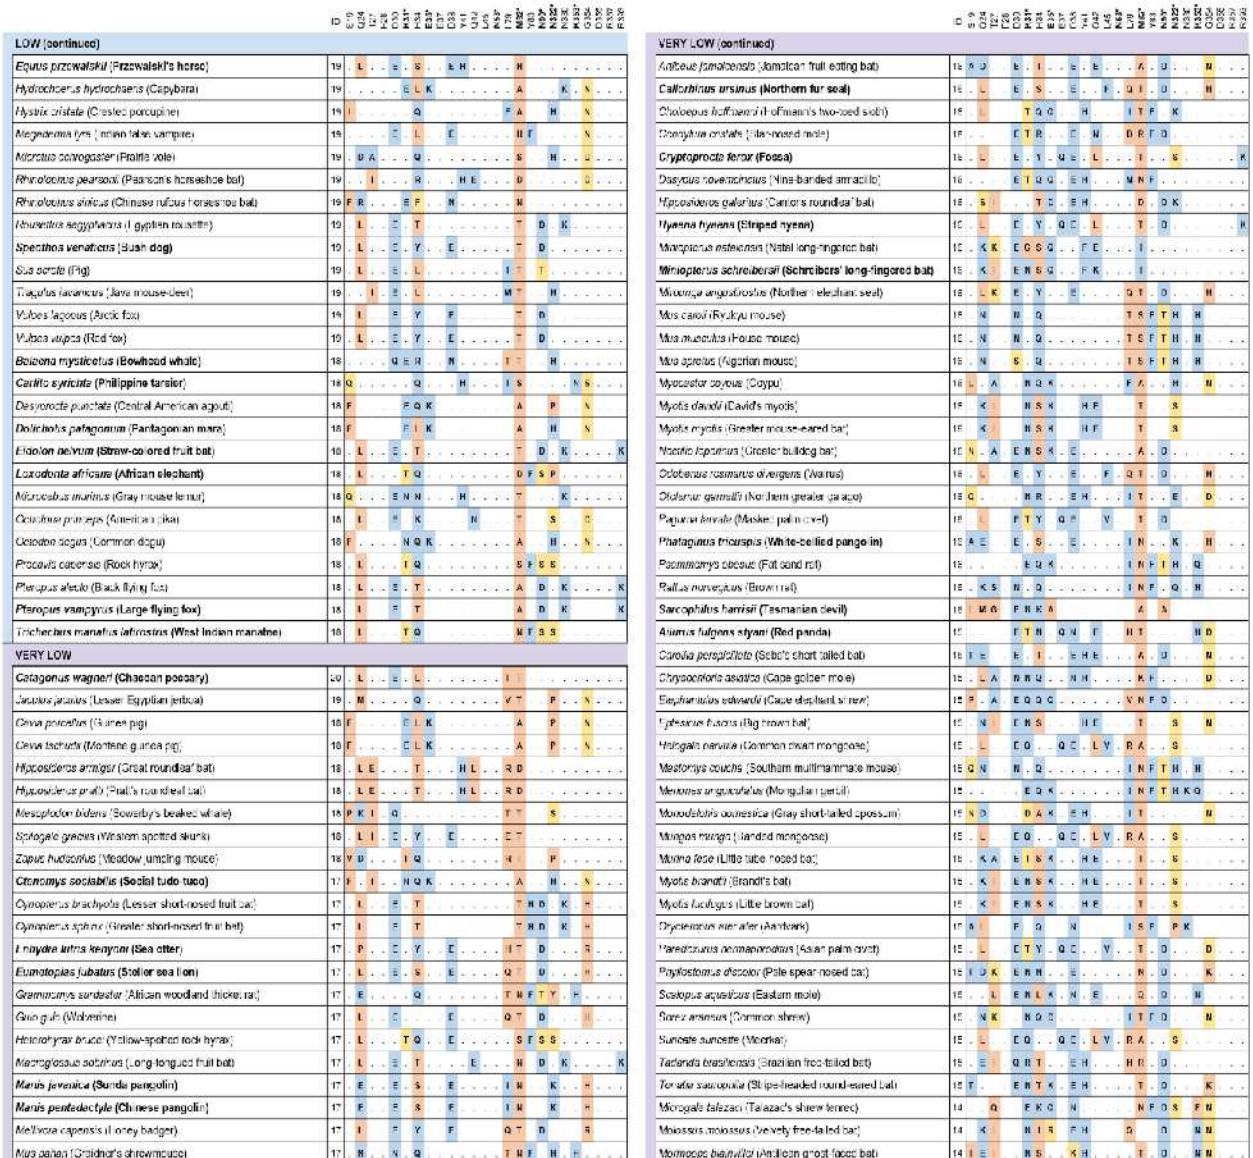


Figure 1. Cross-species conservation of ACE2 and predictions of SARS-CoV-2 susceptibility. Species are sorted by binding score of ACE2 for SARS-CoV-2 S. The 'ID' column depicts the number of amino acids identical to human binding residues. Bold amino acid positions (also labeled with *) represent residues at binding hotspots and constrained in the scoring scheme. Each amino acid substitution is colored according to its classification as non-conservative (orange), semi-conservative (yellow) or neutral (blue), as compared to the human residue. Bold species names depict species with threatened IUCN risk status. The 410 vertebrate species dataset is available in Dataset S1.

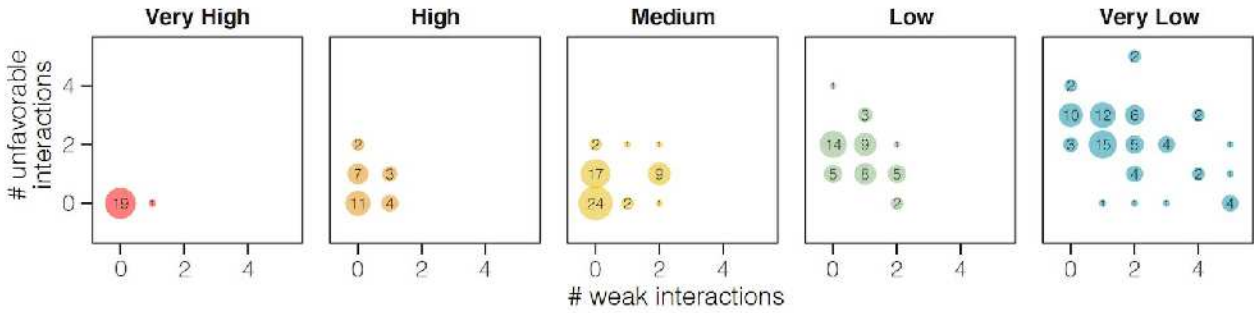

Figure 2. Congruence between binding score and structural homology analysis. Species classified by sequence identity to human ACE2 as *very high* (red) or *high* binding score (orange) have significantly fewer amino acid substitutions rated as potentially altering the binding interface between ACE2 and SARS-CoV-2 through protein structural analysis, as compared to *low* (green) or *very low* (blue) species. The more severe *unfavorable* variants are counted on y-axis and less severe *weaken* variants on the x-axis. Black numerical labels indicate species count.

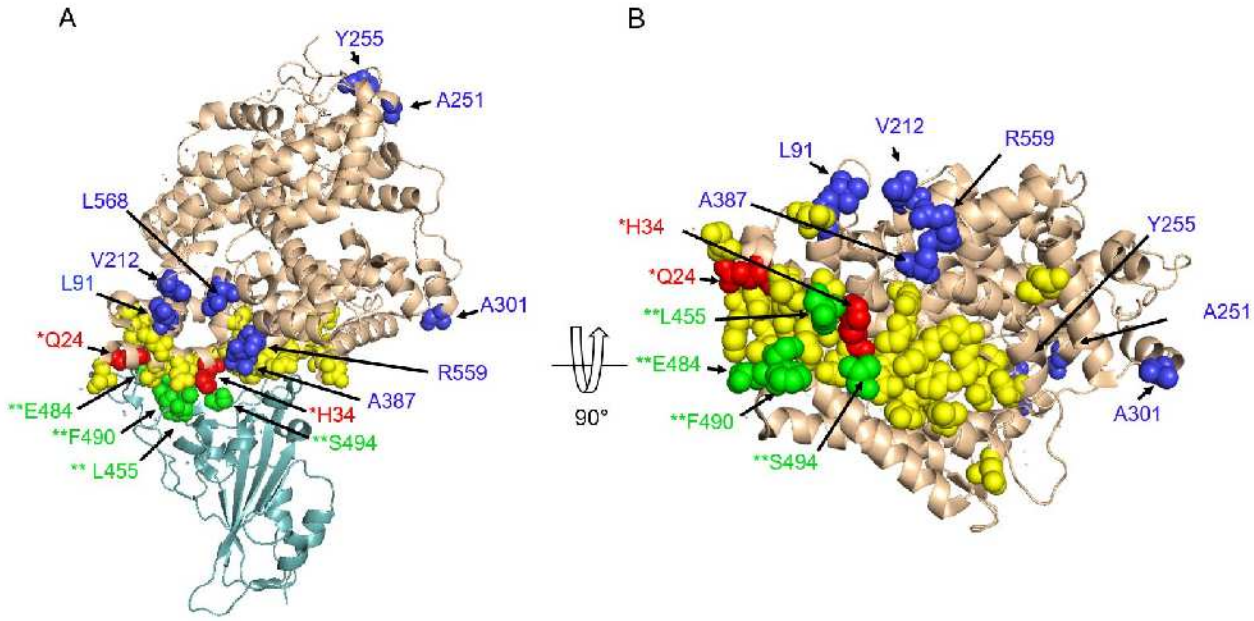

Figure 3. Residues under positive selection detected with CODEML and acceleration with phyloP in mammals. (**A**) ACE2 is represented in wheat cartoon with residues involved in the binding interface shown in yellow spheres. Dark blue and red spheres indicate residues in ACE2 that are accelerated and under positive selection. Red spheres represent residues that overlap with positions in the binding interface and are labeled with (*). The spike RBD is shown in light teal cartoon. Green spheres indicate residues on the SARS-CoV-2 spike protein under positive selection and are labeled with (**). (**B**) 90 degree rotation of the ACE2 protein.

This data, collected pre-COVID19, basically shows that putting on surgical masks can be effective for minimizing the spread of human coronaviruses, although the total number of patients tested was still pretty low and we don't know the extent to which COVID-19 can be spread in aerosolized form. Note that the masks weren't that effective for rhinoviruses or aerosolized flu.

> Hi Jon,
>
> Thanks for passing this along. So others don't have to dig through all of the the 2.5 page table full of abbreviations, here are some scores (matching residues of the 20 key AAs considered) for a few selected species which might be relevant to judging the susceptibility of Myotis lucifugus, which had a score of 11/20:

Homo sapiens (20/20)
Sus scrofa (15/20), in vitro evidence of infection
Mustela putorius furo (15/20), in vivo susceptibility confirmed
Rhinolophus macrotis (13/20), susceptible?
Rhinolophus pusillus (14/20), susceptible?
Rhinolophus ferrumequinum (12/20), susceptible?
Desmodus rotundus (12/20), possibly susceptible (same family as Artibeus, which was not included in the study)?

So, Myotis is relatively low on the list, but so are bats which are related to the presumed reservoir and known susceptible species like ferrets are not too much higher up on the list. I'd be curious to know how others with more knowledge than myself interpret these numbers. Is this measure of ACE-2 affinity something we should use and how low is too low for a host to be susceptible?

Best,
Daniel

This manuscript was compiled on April 12, 2020

The science around the use of masks by the general public to impede COVID-19 transmission is advancing rapidly. Policymakers need guidance on how masks should be used by the general population to combat the COVID-19 pandemic. Here, we synthesize the relevant literature to inform multiple areas: 1) transmission characteristics of COVID-19, 2) filtering characteristics and efficacy of masks, 3) estimated population impacts of widespread community mask use, and 4) sociological considerations for policies concerning mask-wearing. A primary route of transmission of COVID-19 is likely via small respiratory droplets, and is known to be transmissible from presymptomatic and asymptomatic individuals. Reducing disease spread requires two things: first, limit contacts of infected individuals via physical distancing and contact tracing with appropriate quarantine, and second, reduce the transmission probability per contact by wearing masks in public, among other measures. The preponderance of evidence indicates that mask wearing reduces the transmissibility per contact by reducing transmission of infected droplets in both laboratory and clinical contexts. Public mask wearing is most effective at stopping spread of the virus when compliance is high. The decreased transmissibility could substantially reduce the death toll and economic impact while the cost of the intervention is low. Thus we recommend the adoption of public cloth mask wearing, as an effective form of source control, in conjunction with existing hygiene, distancing, and contact tracing strategies. We recommend that public officials and governments strongly encourage the use of widespread face masks in public, including the use of appropriate regulation.

COVID-19 | SARS-CoV-2 | Masks | Pandemic

Policymakers need urgent guidance on the use of masks by the general population as a tool in combating SARS-CoV-2, the respiratory virus that causes COVID-19. Masks have been recommended as a potential tool to tackle the COVID-19 pandemic since the initial outbreak in China (1), although usage during the outbreak varied by time and province (2). Globally, countries are grappling with translating the evidence of public mask wearing to their contexts. These policies are being developed in a complex decision-making environment, with a novel pandemic, rapid generation of new research, and exponential growth in cases and deaths in many areas. There is currently a global shortage of N95 or FFP2 respirators and surgical masks for use in hospitals. Simple cloth masks present a pragmatic solution for use by the public. This has been supported by the United States and European Centres for Disease Control. We present a literature review on the role of simple cloth masks and policies in reducing COVID-19 transmission.

1. Components to Evaluate for Public Mask Wearing

In order to identify whether public mask wearing is an appropriate policy, we need to consider these questions:

1. Do asymptomatic or presymptomatic patients pose a risk of infecting others?
2. Would a face mask likely decrease the number of people infected by an infectious mask wearer?
3. Are there alternative face covers that will not disrupt the medical supply chain, e.g. homemade cloth masks?
4. Will wearing a mask impact the probability of the wearer becoming infected themselves?
5. Does mask use reduce compliance with other recommended strategies, such as physical distancing and quarantine?

Significance Statement

Governments are evaluating the use of non-medical masks in the community amidst conflicting guidelines from health organizations. This review synthesizes available evidence to provide clarity, and advances the use of the 'precautionary principle' as a key consideration in developing policy around use of non-medical masks in public.

Jeremy Howard prepared the initial literature list; Reshama Shaikh prepared the initial literature summaries; Frederik Questier did additional literature searches and summaries; Zhiyuan Li, Violet Tang, Lei-Han Tang, and Danny Hernandez did impact modeling; Zeynep Tufekci provided sociological research and analysis; Helene-Mari van der Westhuizen and Arne von Delft provided analysis of additional impacts; Christina Bax provided review and feedback; All authors contributed to the writing.

Anne W. Rimoin is an editor of the British Medical Journal. Larry F. Chu is a member of the editorial advisory board of the British Medical Journal.

6. Are there any other potential benefits to universal mask wearing such as reducing stigma, signaling solidarity, and increased compliance with other measures?

We will evaluate each consideration in turn.

2. Transmission Characteristics of COVID-19

A primary route of transmission of SARS-CoV-2 is likely via small droplets that are ejected when speaking, coughing or sneezing. The most common droplet size threshold has a minimum at 5 µm to 10 µm (3, 4). There is much debate about whether these droplets should sometimes be considered an aerosol (5). An added complexity is that aerosols are not consistently defined in the literature.

Although earlier studies assumed that droplets were spread mainly through coughing, a more recent analysis has found that transmission through talking may be a key vector, with louder speech creating increasing quantities and sizes of droplets, which are associated with a higher viral load (6).

SARS-CoV-2 is highly transmissible, with a replication number estimated to be approximately 2.4 (7) although estimates vary (8) and will likely change as improved measurements of asymptomatic spread become available. Many COVID-19 patients are asymptomatic, and nearly all have a pre-symptomatic incubation period ranging from 2 to 15 days, with a median length of 5.1 days (9). Patients are most infectious during the initial days of infection (10–15), when symptoms are mildest or not present. This characteristic differentiates SARS-CoV-2 (COVID-19) from SARS-CoV, as replication is activated early in the upper respiratory tract (14, 16). High viral titers of SARS-CoV-2 are reported in the saliva of COVID-19 patients. These titers have been highest at time of patient presentation and viral levels are just as high in asymptomatic or presymptomatic patients (11, 16).

A consequence of these disease characteristics is that any successful intervention policy must properly address transmission due to infectious patients that display few or no symptoms and may not realize that they are infected.

3. Filtering Capability of Masks

Masks can be made of different materials and designs (17) which influence their filtering capability. There are rigorous standards evaluating masks used in healthcare settings but these focus on personal protective equipment (PPE) efficacy, that is, the ability of the mask to protect the wearer from infectious particles. N95 (the American standard; the equivalent in Europe is FFP2) respirators are recommended for health workers conducting aerosol-generating procedures during clinical care of COVID-19 patients. While it has been shown that N95 or FFP2 respirators perform well as PPE, they can become a scarce resource during a pandemic. Toner and Waldhorn (2006) (18) point out that shortages of N95 or FFP2 respirators should be anticipated, and say that if no other masks are available, surgical masks, which will provide droplet protection, should be used. One approach that has been studied for handling N95 or FFP2 respirator shortages is sterilization and re-use, which can be effective (19).

Masks can also be used for source control, which refers to blocking droplets ejected by the wearer, as well as PPE. Although we consider both of these as important, our focus in this paper is on source control, because if everyone is wearing masks to decrease the chance that they themselves are unknowingly infecting someone, everyone ends up being more protected.

Multiple studies show the filtration effects of cloth masks relative to surgical masks. Particle sizes for speech are on the order of 1 µm (20) while typical definitions of droplet size are 5 µm-10 µm (5). Generally available household materials had between a 49% and 86% filtration rate for 0.02 µm exhaled particles whereas surgical masks filtered 89% of those particles (21). In a laboratory setting, household materials had 3% to 60% filtration rate for particles in the relevant size range, finding them comparable to some surgical masks (22). In another laboratory setup, a tea cloth mask was found to filter 60% of particles between 0.02 µm to 1 µm, where surgical masks filtered 75% (23). Dato et al (2006) (24), note that "quality commercial masks are not always accessible." They designed and tested a mask made from heavyweight T-shirts, finding that it "offered substantial protection from the challenge aerosol and showed good fit with minimal leakage".Although cloth and surgical masks are primarily targeted towards droplet particles, some evidence suggests they may have a partial effect in reducing viral aerosol shedding (25).

When considering the relevance of these studies of ingress, it's important to note that they are likely to substantially underestimate effectiveness of masks for source control. When someone is breathing, speaking, or coughing, only a tiny amount of what is coming out of their mouths is already in aerosol form. Nearly all of what is being emitted is droplets. Many of these droplets will then evaporate and turn into aerosolized particles that are 3 to 5-fold smaller. The point of wearing a mask as source control is largely to stop this process from occurring, since big droplets dehydrate to smaller aerosol particles that can float for longer in air (26).

Anfinrud et al (6) used laser light-scattering to sensitively detect droplet emission while speaking. Their analysis showed that virtually no droplets were "expelled" with a homemade mask consisting of a washcloth attached with two rubber bands around the head, while significant levels were expelled without a mask. The authors stated that "wearing any kind of cloth mouth cover in public by every person, as well as strict adherence to distancing and handwashing, could significantly decrease the transmission rate and thereby contain the pandemic until a vaccine becomes available."

An important focus of analysis for public mask wearing is droplet source control. This refers to the effectiveness of blocking droplets from an infectious person, particularly during speech, when droplets are expelled at a lower pressure and are not small enough to squeeze through the weave of a cotton mask. Many recommended cloth mask designs also include a layer of paper towel or coffee filter, which could increase filter effectiveness for PPE, but does not appear to be necessary for blocking droplet emission (6, 27, 28).

In summary, there is laboratory-based evidence that household masks have some filtration capacity in the relevant droplet size range, as well some efficacy in blocking droplets and particles from the wearer (26). That is, these masks help people keep their droplets to themselves.

4. Mask Efficacy Studies

Although no randomized controlled trials (RCT) on the use of masks as source control for SARS-CoV-2 has been published, a number of studies have attempted to indirectly estimate the efficacy of masks. Overall, an evidence review (29) finds "moderate certainty evidence shows that the use of handwashing plus masks probably reduces the spread of respiratory viruses."

The most relevant paper (30), with important implications for public mask wearing during the COVID-19 outbreak, is one that compares the efficacy of surgical masks for source control for seasonal coronavirus, influenza, and rhinovirus. With ten participants, the masks were effective at blocking coronavirus droplets of all sizes for every subject. However, masks were far less effective at blocking rhinovirus droplets of any size, or of blocking small influenza droplets. The results suggest that masks may have a significant role in source control for the current coronavirus outbreak. The study did not use COVID-19 patients, and it is not yet known whether seasonal coronavirus behaves the same as SARS-CoV-2; however, they are of the same genus, so similar behavior is likely.

Another relevant (but under-powered, with n=4) study (31) found that a cotton mask blocked 96% (reported as 1.5 log units or about a 36-fold decrease) of viral load on average, at eight inches away from a cough from a patient infected with COVID-19. If this is replicated in larger studies it would be an important result, because it has been shown (32) that "every 10-fold increase in viral load results in 26% more patient deaths" from "acute infections caused by highly pathogenic viruses".

A comparison of homemade and surgical masks for bacterial and viral aerosols (21) observed that "the median-fit factor of the homemade masks was one-half that of the surgical masks. Both masks significantly reduced the number of microorganisms expelled by volunteers, although the surgical mask was 3 times more effective in blocking transmission than the homemade mask." Research focused on aerosol exposure has found all types of masks are at least somewhat effective at protecting the wearer. Van der Sande et al (33) found that "all types of masks reduced aerosol exposure, relatively stable over time, unaffected by duration of wear or type of activity", and concluded that "any type of general mask use is likely to decrease viral exposure and infection risk on a population level, despite imperfect fit and imperfect adherence". Overall however, analysis of particle filtration is likely to underestimate the effectiveness of masks, since the fraction of particles that are emitted as aerosol (vs. droplet) is quite small (26). Analysis of seasonal coronavirus compared to rhinovirus (30) suggests that filtration of COVID-19 may be much more effective, especially for source control.

The importance of using masks for health care workers has been observed (34) in three Chinese hospitals where, in each hospital, medical staff wearing masks (mainly in quarantine areas) had no COVID-19 infections, despite being around COVID-19 patients far more often, whilst other medical staff had 10 or more infections in each of the three hospitals.

Masks seem to be effective for source control in the controlled setting of an airplane. One case report (35) describes a man who flew from China to Toronto and then tested positive for COVID-19. He was wearing a mask during the flight. The 25 people closest to him on plane/flight attendants were tested and all were negative. Nobody has been reported from that flight as getting COVID-19. Another case study involving a masked influenza patient on an airplane (36) found that "wearing a face mask was associated with a decreased risk for influenza acquisition during this long-duration flight".

Guideline development for health worker personal protective equipment have focused on whether surgical masks or N95 respirators should be recommended. Most of the research in this area focuses on influenza. At this point, it is not known to what extent findings from influenza studies apply to COVID-19 filtration. Wilkes et al (37) found that "filtration performance of pleated hydrophobic membrane filters was demonstrated to be markedly greater than that of electrostatic filters." However, even substantial differences in materials and construction do not seem to impact the transmission of droplet-borne viruses in practice, such as a meta-analysis of N95 respirators compared to surgical masks (38) that found "the use of N95 respirators compared with surgical masks is not associated with a lower risk of laboratory-confirmed influenza." Johnson et al (39) showed that "surgical and N95 masks were equally effective in preventing the spread of PCR-detectable influenza". Radonovich et al (40) found in an outpatient setting that "use of N95 respirators, compared with medical masks... resulted in no significant difference in the rates of laboratory-confirmed influenza."

One of the most frequently mentioned papers evaluating the benefits and harms of cloth masks have been by MacIntyre et al (41). Findings have been misinterpreted, and therefore justify detailed discussion here. The authors "caution against the use of cloth masks" for healthcare professionals compared to the use of surgical masks and regular procedures, based on an analysis of transmission in hospitals in Hanoi. We emphasize the setting of the study - health workers using masks to protect themselves against infection. The study compared a "surgical mask" group which received 2 new masks per day, to a "cloth mask" group that received 5 masks for the entire 4 week period and were required to wear the masks all day, to a "control group" which used masks in compliance with existing hospital protocols, which the authors describe as a "very high level of mask use". It is important to note that the authors did not have a "no mask" control group because it was deemed "unethical to ask participants to not wear a mask." The study does not inform policy pertaining to public mask wearing as compared to the absence of masks in a community setting, since there is not a "no mask" group. The results of the study show that the group with a regular supply of new surgical masks each day had significantly lower infection of rhinovirus than the group that wore a limited supply of cloth masks. This paper lends support to the use of clean, surgical masks by medical staff in hospital settings to avoid rhinovirus infection by the wearer, and is consistent with other studies that show cloth masks provide poor filtration for rhinovirus (30). Its implementation does not inform the effect of using cloth masks versus not using masks in a community setting for source control of SARS-CoV-2, which is of the same genus as seasonal coronavirus, which has been found to be effectively filtered by cloth masks in a source control setting (30).

A. Studies of Impact on Community Transmission. When evaluating the available evidence for the impact of masks on community transmission, it is critical to clarify the setting of the research study (health care facility or community), the res-

piratory illness being evaluated and what reference standard was used (no mask or surgical mask). There are no RCTs that have been done to evaluate the impact of masks on community transmission during a coronavirus pandemic. While there is some evidence from influenza outbreaks, the current global pandemic poses a unique challenge. A review (42) of 67 studies including randomized controlled trials and observational studies found that simple and lowcost interventions would be useful for reducing transmission of epidemic respiratory viruses. The review recommended that "the following effective interventions should be implemented, preferably in a combined fashion, to reduce transmission of viral respiratory disease: 1. frequent handwashing with or without adjunct antiseptics; 2. barrier measures such as gloves, gowns, and masks with filtration apparatus; and 3. suspicion diagnosis with the isolation of likely cases". However, it cautioned that routine longterm implementation of some measures assessed might be difficult without the threat of an epidemic.

Seuess et al conducted an RCT (43)that suggests household transmission of influenza can be reduced by the use of non-pharmaceutical interventions, namely the use of face masks and intensified hand hygiene, when implemented early and used diligently. Concerns about acceptability and tolerability of the interventions should not be a reason against their recommendation (43). Cowling et al (44) investigated hand hygiene and face masks in an RCT that seemed to prevent household transmission of influenza virus when implemented within 36 hours of index patient symptom onset. These findings suggest that non-pharmaceutical interventions are important for mitigation of pandemic and inter-pandemic influenza.

RCT findings by Aiello et al (45) "suggest that face masks and hand hygiene may reduce respiratory illnesses in shared living settings and mitigate the impact of the influenza A (H1N1) pandemic". A randomized intervention trial (46) found that "face masks and hand hygiene combined may reduce the rate of ILI [influenza-like illness] and confirmed influenza in community settings. These non-pharmaceutical measures should be recommended in crowded settings at the start of an influenza pandemic." The authors noted that their study "demonstrated a significant association between the combined use of face masks and hand hygiene and a substantially reduced incidence of ILI during a seasonal influenza outbreak. If masks and hand hygiene have similar impacts on primary incidence of infection with other seasonal and pandemic strains, particularly in crowded, community settings, then transmission of viruses between persons may be significantly decreased by these interventions."

An observational study in Hong Kong on SARS (47) found "frequent mask use in public venues, frequent hand washing, and disinfecting the living quarters were significant protective factors (OR 0.36 to 0.58)". An important observation was that "members of the case group [infected with SARS] were less likely than members of the control group [not infected] to have frequently worn a face mask in public venues (27.9% vs. 58.7%)".

B. Implementation and Sociolological Considerations. For a novel disease where much is unknown, it is important to examine the context of studies closely and also distinguish "absence of evidence" from "evidence of absence" (2). We discuss estimates of cloth mask filtering performance in Filtering Capability of Masks and summarize modelling on population impact in Estimating Population Impacts.

Some of the concerns about public mask wearing have not been around primary evidence for the efficacy of source control, but concerns about how they will be used. We present some considerations for the translation of evidence about public mask wearing to diverse countries across the globe, outside of the parameters of a controlled research setting:

B.1. Supply chain management of N95 respirators and surgical masks. There has been a global shortage of protective equipment for health workers, with health workers falling ill and dying of occupationally acquired COVID-19 disease (48). Public messaging encouraging mask use and depleting critical supplies have been a major concern. Some regions, like South Korea and Taiwan, have decided to promote surgical mask use on a mass scale and opted to address potential stock issues through rapidly increasing production of surgical masks. In regions where surgical mask supplies are scarce, cloth masks may be a pragmatic temporary alternative to surgical masks for the public.

B.2. Sociological considerations and anticipating population-level behavior changes. It is difficult to predict the behavior change that would accompany regulations encouraging public mask use. One concern around public health messaging promoting the use of face-covering has been that members of the public may use risk compensation behavior and neglect physical distancing based on overvaluing the protection a surgical mask may offer due to an exaggerated or false sense of security (49). Similar arguments have previously been made for HIV prevention strategies (50) (51) and other safety devices and mandates such as motorcycle helmet laws (52) and seat-belts (53). However, research on these topics finds no such increase in adverse outcomes at the population level but rather improvements in safety and well-being, suggesting that even if risk compensation occurs in some individuals, that effect is dwarfed by the increased safety at the population level (53, 54). Further, even for deliberately high-risk recreational activities such as alpine skiing and snowboarding, wearing a helmet was generally associated with risk reduction oriented-behavior (55), suggesting safety devices are both compatible with and perhaps encourage safety-oriented behavior. Even for high-risk recreational activities like alpine skiing and snowboarding, helmet use has greatly reduced injury rates (56).

In general, various forms of risk compensation theories have been proposed for many different safety innovations, but have been not found to have empirical support (57) at the population level. These findings strongly suggest that, instead of withholding a preventative tool, accompanying it with accurate messaging that combines different preventative measures would display trust in the general public's ability to act responsibly and empower citizens, and risk compensation is unlikely to undo the positive benefits at the population level (58).

At the height of the 2009 influenza epidemic in Mexico City it was found (59) that mandatory mask requirements increased compliance compared to voluntary recommendations. Voluntary compliance was strongly influenced by public perception regarding the effectiveness of the recommended measures.

For many infectious diseases, including, for example, tuberculosis, health authorities recommend masks only for those

infected or people who are taking care of someone infected. However, research shows that many sick people are reluctant to wear a mask if it identifies them as sick, and thus end up not wearing them at all in an effort to avoid the stigma of illness (60, 61). Stigma is a powerful force in human societies, and many illnesses come with stigma for the sick as well as fear of them, and managing the stigma is an important part of the process of controlling epidemics as stigma also leads to people avoiding treatment as well as preventive measures that would "out" their illness (62). Many health authorities have recommended wearing masks for COVID-19 only if people are sick; however, reports of people wearing masks being attacked, shunned and stigmatized have already been observed (63). Having masks worn only by the suspected/confirmed infected also has led to employers in high-risk environments like grocery stores and prisons, and even hospitals, banning employees from wearing one sometimes with the idea that it would scare the customer or the patients (64, 65). Further, in many countries, minorities suffer additional stigma and assumptions of criminality (66). In that vein, black people in the United States have reported that they were reluctant to wear masks in public during this pandemic for fear of being mistaken as criminals (67, 68). Even if it were possible to encourage only infected people to wear masks, given the lack of access to testing in many countries, it is not possible for many people to know for sure if they are infected or not (69). Thus, while this paper has shown the importance of masks for source-control – preventing asymptomatic and presymptomatic people from infecting others – it may not even be possible to have infected/sick people wear masks due to stigma, employer restrictions, or simple lack of knowledge of ones status without mask-wearing becoming universal policy.

Another important benefit of recommending universal mask wearing would be to serve as a visible signal and reminder of the pandemic, and given the importance of ritual and solidarity in human societies (70), it is plausible that visible, public signaling via mask wearing can potentially increase compliance with other health measures as well, such as keeping distance and hand-washing. Health, especially during an epidemic, is a form of public good in that everyone else's health behaviors improve the health odds of everyone else, and that it is non-rivalrous in that one person's health does not diminish the health of anyone else (71, 72). Visible signals play an important role in human societies (73). As such, signaling participation in health behaviors by wearing a mask as well as visible enforcement (for example, shops asking customers to wear masks) can increase compliance (74). Further, historically epidemics are a time of fear, confusion and helplessness (75, 76). Mask-wearing and even mask-making or distribution can provide feelings of empowerment and self-efficacy (77), which would in turn also suggest masks could increase compliance in other health-behaviors as well by increasing self-efficacy. In Hong Kong, for example, a community-driven focus on epidemic prevention started in the early days of COVID-19, and included community activists acquiring and distributing masks especially to those without resources and the elderly, even before it was officially declared a pandemic or before their own government had taken strong steps (78). Currently, Hong Kong has not only a relatively contained epidemic compared with many other countries, but a significant reduction in influenza cases as well which their health authorities attribute, among other factors, to the near-universal mask wearing and strong norms around it (79–81).

C. Universal or near-universal mask wearing. Estimating adherence to regulations for public mask wearing is a key input for modeling the impact of public mask wearing. Telephone surveys during the SARS-CoV-2 outbreak in Hong Kong reported enhanced adherence to public mask wearing as the pandemic progressed over three weeks, with 74.5% self reported mask wearing when going out increasing to 97.5%, without mandatory requirements (82). Similar surveys reported face mask use in Hong Kong during the SARS outbreak in 2003 as 79% (83), and approximately 10% during the influenza A(H1N1) pandemic in 2009 (84). This suggests that the public have enhanced awareness of their risk, and display higher adherence levels to prevention strategies than during other epidemics. Cloth masks could be an additional tool to enhance awareness of the importance of physical distancing in public places, serving as a visual reminder. Should masks be reserved solely for use in symptomatic patients, they become a symbol of illness and could lead to public stigmatization that discourages use, as has been described for patients with tuberculosis (61). Countries like the Czech Republic and Hong Kong offer interesting perspectives on the role of citizen advocacy and on the acceptability of face-covering in public.

D. Balancing potential harm of cloth masks with additional benefits for concurrent epidemic. Based on our detailed discussion above, cloth masks have not been shown to increase the risk of infection in people using them compared to not wearing any mask. While the focus of this article has been on preventing the spread of COVID-19 disease through public mask wearing, many low-middle income countries face concurrent epidemics of diseases like tuberculosis. Tuberculosis kills 1.5 million people globally per year, and in 2018, 10 million people fell ill (85). Face covering has been shown to also reduce the transmission of tuberculosis (86) and offer additional benefits to public mask wearing. Similarly, influenza transmissibility in the community was found to have declined by 44% in Hong Kong after the implementation of changes in population behaviors, including social distancing and increased mask wearing, enforced in most stores, during the COVID-19 outbreak (82).

It has been noted (87) that ensuring compliance with non-pharmaceutical interventions can be challenging: "Mask wearing is a promising non-pharmaceutical intervention to reduce risk of secondary transmission of viral URI [upper respiratory infections], but it is likely that adherence to mask wearing would occur only if there was a major pandemic that resulted in a heightened level of community concern and fear." Many regions have now passed laws to ensure compliance. The first RCT (2008) on mask use (88) "found compliance to be low, but compliance is affected by the perception of risk. In a pandemic, we would expect compliance to improve." The authors noted that "in compliant users, masks were highly efficacious."

5. Estimating Population Impacts

At the national and global scale, effective local interventions are aggregated into epidemiological parameters of disease spread. The standard epidemiological measure of spread is known as the reproduction number R_0 which parameterizes

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 12 April 2020 doi:10.20944/preprints202004.0203.v1

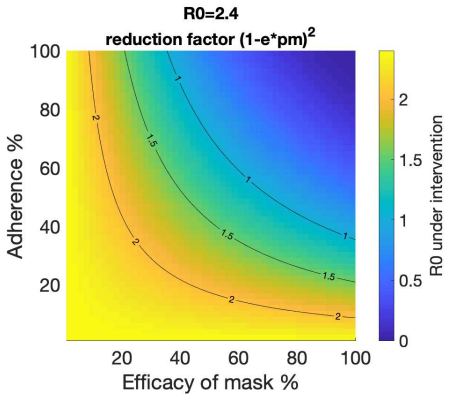

Fig. 1. Impact of public mask wearing under the full range of mask adherence and efficacy scenarios. The color indicates the resulting reproduction number R_0 from an initial R_0 of 2.4 (7).

the number of cases infected by one case,in a completely susceptible population. R_0 determines the rate of growth, with a superlinear effect. The goal of any related healthcare policy is to have an aggregate effect of reducing R_0 to below 1.0.

Efficacy of face masks within local interventions would have an aggregate effect on the reproduction number of the epidemic. What is the magnitude of such an effect? The HKBU COVID-19 Modelling Group developed a transmission model that incorporated mask wearing and mask efficacy as a factor in the model (89). They estimate reductions in the basic reproduction number R_0 under common intervention measures. For wearing masks, they find that wearing masks reduces R_0 by a factor $(1 - ep_m)^2$, where e is the efficacy of trapping viral particles inside the mask, and p_m is the percentage of the population that wears masks. When combined with contact tracing, the two effects multiply.

A conservative assessment applied to the COVID-19 estimated R_0 of 2.4 (7) might posit 50% mask usage and a 50% mask efficacy level, reducing R_0 to 1.35, an order of magnitude impact rendering spread comparable to the reproduction number of seasonal influenza. To put this in perspective, 100 cases at the start of a month becomes 31,280 cases by the month's end ($R_0 = 2.4$) vs. only 584 cases ($R_0 = 1.35$). Such a slowdown in case-load protects healthcare capacity and renders a local epidemic amenable to contact tracing interventions that can eliminate the spread entirely.

A full range of efficacy e and adherence p_m is shown with the resulting R_0 in Figure 1, illustrating regimes in which growth is halted entirely ($R_0 < 1$) as well as pessimistic regimes (e.g. due to poor implementation or population compliance) that nonetheless result in a beneficial effect in suppressing the exponential growth of the pandemic.

Yan et al (90) provide an additional example of an incremental impact assessment of respiratory protective devices using an augmented variant of a traditional SIR model in the context of influenza with N95 respirators. They showed that a sufficiently high adherence rate (~ 80% of the population) resulted in the elimination of the outbreak with most respiratory protective devices.

Qualitative comparisons of outcomes between countries (91, 92) are suggestive of policy differences leading to differences in disease spread of up to three orders of magnitude. Although between-country comparisons do not allow for causal attribution, they suggest mask wearing to be a low-risk measure with a potentially large positive impact, with many countries with widespread use of masks in public keeping deaths below one in a million.

Abaluck et al (93) extend the between-country analyses from a cost perspective, estimating the marginal benefit per cloth mask worn to range from $3,000-$6,000. They also found that "the average daily growth rate of confirmed positives is 18% in countries with no preexisting mask norms and 10% in countries with such norms." and "that the growth rate of deaths is 21% in countries with no mask norms and 11% in countries with such norms."

6. Discussion and Recommendations

Our review of the literature offers evidence in favor of widespread mask use to reduce community transmission: non-medical masks use materials that obstruct droplets of the necessary size; people are most infectious in the initial period post-infection, where it is common to have few or no symptoms (10–16); non-medical masks have been effective in reducing transmission of influenza; non-medical masks have been shown to be effective in small trials at blocking transmission of coronavirus; and places and time periods where mask usage is required or widespread have shown substantially lower community transmission.

The available evidence suggests that near-universal adoption of non-medical masks when out in public, in combination with complementary public health measures could successfully reduce effective-R to below 1.0, thereby stopping community spread. Economic analysis suggests that the impact of mask wearing could be thousands of US dollars saved per person per mask (93).

Interventions to reduce COVID-19 spread should be prioritized in order of their expected multiple on effective R divided by their cost. By this criterion experimentation with and deployment of universal masks look particularly promising. When used in conjunction with widespread testing, contact tracing, quarantining of anyone that may be infected, hand washing, and physical distancing, face masks are a valuable tool to reduce community transmission. All of these measures, through their effect on R_0, have the potential to reduce the period of lockdown required. As governments talk about relaxing lockdowns, keeping transmissions low enough to preserve health care capacity will be critical until a vaccine can be developed. Mask wearing may be critical to preventing a second wave of infections from overwhelming the health care system – further research is urgently needed here.

UNESCO states that "when human activities may lead to morally unacceptable harm that is scientifically plausible but uncertain, actions shall be taken to avoid or diminish that harm" (94). This is known as the "precautionary principle". The World Charter for Nature, which was adopted by the UN General Assembly in 1982, was the first international endorsement of the precautionary principle. It was implemented in an international treaty in the 1987 Montreal Protocol. The loss of life and economic destruction that has been seen already from COVID-19 is a "morally unacceptable harm". The positive impact of public mask wearing on this is "scientifically plausible but uncertain". This notion is reflected in Figure 1 - while researchers may reasonably disagree on the magnitude of transmissibility reduction and compliance, seemingly

modest benefits can be massively beneficial in the aggregate due to the exponential character of the transmission process. Therefore, the action of ensuring widespread use of masks in the community should be taken, based on this principle (95).

Models suggest that public mask wearing is most effective at stopping spread of the virus when compliance is high. This is the same situation as we see with vaccines - the more people are vaccinated, the higher the benefit to the whole population including those who cannot be vaccinated like infants or immuno-compromised people. A common policy response to this conundrum is to ensure compliance by using laws and regulations, such as widespread state laws in the US which require vaccinations to attend school. Research shows that the strength of the mandate to vaccinate greatly influences compliance rates for vaccines and that policies that set a higher bar for vaccine exemptions result in higher vaccination rates. (96) The same approach is now being used in many jurisdictions to increase mask wearing compliance, by mandating mask use in a variety of settings (such as public transportation or grocery stores or even at all times outside the home). Early results suggest that these laws are effective at increasing compliance and slowing or stopping the spread of COVID-19 (91). We recommend that mask use requirements are implemented by governments, or when governments do not, by organizations that provide public-facing services, such as transit service providers or stores, as "no mask, no service" rules. Such mandates must be accompanied by measures to ensure access to masks, possibly including distribution and rationing mechanisms so that they do not become discriminatory but remain focused on the public health benefit. Given the value of the source control principle, especially for presymptomatic people, it is not good enough for only employees to wear masks, customers must wear masks as well.

It is also important for health authorities to provide clear guidelines for the production, use and sanitization or re-use of face masks, and consider their distribution as shortages allow. A number of countries have distributed surgical masks (South Korea, Taiwan) from early on while Japan and Singapore are now distributing cloth masks to their whole population. Clear and implementable guidelines can help increase compliance, and bring communities closer to the goal of reducing and ultimately stopping the spread of COVID-19.

Materials and Methods

A community-driven approach was used for building the paper list used in this literature review. A multidisciplinary community of researchers used online tools to review and actively discuss publications related to the question of the effectiveness and policy of public mask wearing.

Wow, I just barely made the cutoff! Did we loose anyone on the far right!?

It was an amazing trip Supaporn! I speak on behalf of all the BPERNet and PMAC delegates when I say THANK YOU !

You and the team did an amazing job organizing this.

Best regards,
Kevin

Subject: Final BPERNet Read-out

All,

Please find the final BPERNet read-out for your files. To everyone who provided feedback, we thank you very much for your responses.

A couple housekeeping items:

1. In the next several weeks, we will begin making plans for our next meeting to take place around the One Health Congress in Saskatoon, Canada.

The event feedback you provided will help shape this event and that we anticipate building a 2-day program that includes a scenario-based exercise and presentations.

2. One action item from our Bangkok meeting was to begin discussion about a new name for the network; **please participate in this survey monkey poll to find our new name https://www.surveymonkey.com/r/PQXTHCV**. Please note that the group's will assist the group with establishing a web presence for better communications and outreach, so we depend on your feedback to meet these goals. Please let us know through the survey if you do not feel we are using the right words to communicate the group's core mission.

Thank you again for your participation in these polls and feedback on the report. Please let us know if you have any questions or concerns.

Hi Kevin,

Very nice job on this! Only spotted a couple small things.
1) "highlights" is misspelled on line 128.
2) looks like a ref is still needed in line 342 regarding PPE usage in the field. This ref might fit...it's more broadly on wildlife professionals though (PMID: 31993824)
3) don't forget to delete the [...] on line 421

Yes, I would be delighted to be a co-author.

My ORCID is 0000-0002-4996-915X.

Thanks so much!
Rebekah

Subject: Final version of North American bat/SARS2 ms - PLEASE REVIEW

Dear Esteemed Colleagues,

Please review the attached penultimate draft of our manuscript (now entitled: " **Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats")**, together with the supplementary table and refs. Our plan is to submit to *Lancet Infectious Diseases* as a review article (correct length and they allow 150 refs) in the next week - references are currently formatted for that journal. We would also like to post it on bioRxiv as a pre-print once we get it submitted to *Lancet ID*. Please let me know if you have any concerns with that plan.

Thank you all for your excellent comments and edits on the previous draft. Paul and I have gone back and forth on several rounds of revisions since then (and multiple late night texts), aiming to take each and every suggestion into account, and we believe it's a much better manuscript now! Very excited about this one, and looking forward to getting it published!

By Thursday April 30th (or ASAP), could you each please:

1. Confirm that you agree to be a co-author.
2. Double check your name and affiliation, and send me your ORCID number if you have one.
3. Read through the ms and send any important, last minute changes or edits you feel are necessary. Please use track changes. If you're okay with the ms as is, please just confirm so.
4. For my Federal US Gov't friends (USFWS, USGS, CDC, USDA) - please let us know what we need to do for approval on your end. I know Paul is working with USGS now to hopefully get rapid clearance.

No need to cc all if you don't want, but please include both me and Paul on your response.

Looking forward to hearing from you all soon!

Cheers,
Kevin and Paul

Hi Katie et al.,

I too strongly support the January meeting for the reasons that Jon outlined and also because my teaching is in the fall semester and it would be hard for me to attend the meeting in Doha.

I support Jon's RABEZ suggestion. In reference to our colleagues in bat conservation, we need to have the pathogen component in the title. And, we can't, from a grammatical perspective be an alliance FOR bat pathogens, rather an alliance for the study of bat pathogens.

Thanks, DeeAnn

Greetings, GBA Steering Committee!

As promised we compiled a couple products and action items from our inaugural meeting on the 29th.

The All Partners Access Network (the site we will use for document sharing and editing) is live and the Executive Summary from our meeting, revised TORFTA, and TORFTA editing sheet have been uploaded. Here are the directions for access:

1. Go to www.apan.org
2. Click, “Create Account” (green button, upper right)
3. Use preferred work email and create password
4. Notify Will Sander once you have created your account; he will invite you to join the GBA SharePoint

For your ease, I have also attached the products that were hung on APAN:

1. An Executive Summary of the 29 June meeting for your files. This lists out key discussions, action items, and participants from the meeting.
2. Revised TORFTA (v14); **NOTE:** the plan for this document is to open a one week editing period for comments. If possible, edits and comments are due back NLT 31 July. After that, the official Version 1 of the GBA will be published.

Here are some requests that we have of you; if you have ideas on any or all of these items, please respond to this email:

1. We need suggestions for a next meeting and would like your suggestions; we will plan to release all options to the group in one week from now for vote. Here are some suggestions to get us started:
   a. International Congress on Pathogens at the Human and Animal Interface (ICOPHAI) 7-9 November 2017, Doha, Qatar https://icophai.org/
   b. Participatory Epidemiology Network for Animal and Public Health (PENAPH) – 10-12 January 2018, Chiang Mei, Thailand https://penaph.net/second-penaph-conference-participatory-approaches-in-animal-health-public-health-one-health-and-ecohealth/
   c. Others??
2. We need suggestions for Network names and would like your suggestions; we will plan to release the options to the group in one week from now for vote. Here are some suggestions to get us started:
   a. Global Alliance for Bat-borne Pathogens (GABP)
   b. Global Bat Pathogen Disease Network (GBPDN)
   c. Bat Alliance Trust Disease Network (BAT-DN)
   d. Others??
3. We need nominations for co-chairs, seek your suggestions; we will plan to release nominees in one week from now for vote.

My RABEZ suggestion was slightly tongue-in-cheek. In retrospect, I worry that it might be outwardly confusing to others if we become the "Rabies network" when we won't actually be doing much with rabies.
With sensitivity to the bat conservation community, I suggest the "Bat Viral Ecology Research Network" or something along that line.

Cheers,
Jon

Here are some requests that we have of you; if you have ideas on any or all of these items, please respond to this email:

1. We need suggestions for a next meeting and would like your suggestions; we will plan to release all options to the group in one week from now for vote. Here are some suggestions to get us started:
    a. International Congress on Pathogens at the Human and Animal Interface (ICOPHAI) 7-9 November 2017, Doha, Qatar https://icophai.org/
    b. Participatory Epidemiology Network for Animal and Public Health (PENAPH) – 10-12 January 2018, Chiang Mei, Thailand https://penaph.net/second-penaph-conference-participatory-approaches-in-animal-health-public-health-one-health-and-ecohealth/
    c. Others??
2. We need suggestions for Network names and would like your suggestions; we will plan to release the options to the group in one week from now for vote. Here are some suggestions to get us started:
    a. Global Alliance for Bat-borne Pathogens (GABP)
    b. Global Bat Pathogen Disease Network (GBPDN)
    c. Bat Alliance Trust Disease Network (BAT-DN)
    d. Others??
3. We need nominations for co-chairs, seek your suggestions; we will plan to release nominees in one week from now for vote.

Dear Katie, Dear Colleagues,

Thank you for your email.
I have successfully created an APAN account.
As for network name -I like Mary's suggestion - Bat-associated Pathogen and Ecology Research Network, or Global Alliance for Bat-born Pathogens (GBAP)
For the next meeting I vote for (PENAPH) Thailand.

Yours sincerely,

Tamar

Greetings, GBA Steering Committee!

As promised we compiled a couple products and action items from our inaugural meeting on the 29th.

The All Partners Access Network (the site we will use for document sharing and editing) is live and the Executive Summary from our meeting, revised TORFTA, and TORFTA editing sheet have been uploaded. Here are the directions for access:

1. Go to www.apan.org
2. Click, "Create Account" (green button, upper right)
3. Use preferred work email and create password
4. Notify Will Sander once you have created your account; he will invite you to join the GBA SharePoint

For your ease, I have also attached the products that were hung on APAN:

1. An Executive Summary of the 29 June meeting for your files. This lists out key discussions, action items, and participants from the meeting.
2. Revised TORFTA (v14); **NOTE:** the plan for this document is to open a one week editing period for comments. If possible, edits and comments are due back NLT 31 July. After that, the official Version 1 of the GBA will be published.

Here are some requests that we have of you; if you have ideas on any or all of these items, please respond to this email:

1. We need suggestions for a next meeting and would like your suggestions; we will plan to release all options to the group in one week from now for vote. Here are some suggestions to get us started:
    a. International Congress on Pathogens at the Human and Animal Interface (ICOPHAI) 7-9 November 2017, Doha, Qatar https://icophai.org/
    b. Participatory Epidemiology Network for Animal and Public Health (PENAPH) – 10-12 January 2018, Chiang Mei, Thailand https://penaph.net/second-penaph-conference-participatory-approaches-in-animal-health-public-health-one-health-and-ecohealth/
    c. Others??

Dear Katie and all,

I have set up the APAN account, and confirmed with Will Sander.

I also support PMAC in Thailand (end of Jan) as a good meeting suggestion, and already plan to attend this. I would available for Doha (ICOPHAI) too if others/DTRA feel this is best.

Good name suggestions out there. I also thought Jon's RABEZ suggestion was clever, but agree with him it could cause some confusion. I really like Mary's recent suggestion of: **Bat-associated Pathogen and Ecology Research Network (BPERN).** Think this accurately captures the focus on pathogens and also the ecology of those pathogens, and avoids confusion with the conservation community that the more generic names caused.

Cheers,
Kevin

I've been in TX too long, I gave it a Spanish pronunciation and missed the rabies thing entirely haha!

Subject: Re: GBA Products and Action Items

My RABEZ suggestion was slightly tongue-in-cheek. In retrospect, I worry that it might be outwardly confusing to others if we become the "Rabies network" when we won't actually be doing much with rabies.
With sensitivity to the bat conservation community, I suggest the "Bat Viral Ecology Research Network" or something along that line.

Cheers,
Jon

I support Jon's RABEZ suggestion. In reference to our colleagues in bat conservation, we need to have the pathogen component in the title. And, we can't, from a grammatical perspective be an alliance FOR bat pathogens, rather an alliance for the study of bat pathogens.

Thanks, DeeAnn

> Hi Katie,
> I propose meeting at the Prince Mahidol Award Conference (PMAC) in Bangkok, late January 2018. Primarily, I think November might be slightly early for our next meeting, given that we're working through governance and committee population. Also, PMAC is a big One Health meeting that at least three of us on the steering committee will already be attending, so there's some efficiency to it in terms of scheduling and expense, as well as having thematic relevance to our group.

Dear Katie,

Thank you much for your e-mail and the provided documents.

I have successfully created an APAN account.

Regarding the name of the network, I prefer the following name: Global Bat Pathogen Disease Network (GBPDN).

For the next meeting, I vote for “Participatory Epidemiology Network for Animal and Public Health (PENAPH)” conference that will be held in Thailand next January.

My best regards,

Nisreen

Note: this email is best viewed in HTML

Greetings, GBA Steering Committee!

As promised we compiled a couple products and action items from our inaugural meeting on the 29 th.

The All Partners Access Network (the site we will use for document sharing and editing) is live and the Executive Summary from our meeting, revised TORFTA, and TORFTA editing sheet have been uploaded. Here are the directions for access:

1. Go to www.apan.org
2. Click, “Create Account” (green button, upper right)
3. Use preferred work email and create password
4. Notify Will Sander once you have created your account; he will invite you to join the GBA SharePoint

For your ease, I have also attached the products that were hung on APAN:

1. An Executive Summary of the 29 June meeting for your files. This lists out key discussions, action items, and participants from the meeting.
2. Revised TORFTA (v14); **NOTE:** the plan for this document is to open a one week editing period for comments. If possible, edits and comments are due back NLT 31 July. After that, the official Version 1 of the GBA will be published.

Here are some requests that we have of you; if you have ideas on any or all of these items, please respond to this email:

1. We need suggestions for a next meeting and would like your suggestions; we will plan to release all options to the group in one week from now for vote. Here are some suggestions to get us started:
   a. International Congress on Pathogens at the Human and Animal Interface (ICOPHAI) 7-9 November 2017, Doha, Qatar https://icophai.org/
   b. Participatory Epidemiology Network for Animal and Public Health (PENAPH) – 10-12 January 2018, Chiang Mei, Thailand https://penaph.net/second-penaph-conference-participatory-approaches-in-animal-health-public-health-one-health-and-ecohealth/
   c. Others??
2. We need suggestions for Network names and would like your suggestions; we will plan to release the options to the group in one week from now for vote. Here are some suggestions to get us started:
   a. Global Alliance for Bat-borne Pathogens (GABP)
   b. Global Bat Pathogen Disease Network (GBPDN)
   c. Bat Alliance Trust Disease Network (BAT-DN)
   d. Others??
2. We need nominations for co-chairs, seek your suggestions; we will plan to release nominees in one week from now for vote.

Subject: RE: GBA Products and Action Items

Greetings everyone
Jon is there a link for the Prince Mahidol Award Conference (PMAC)? And dates? I will be teaching that semester, and it can be a bit manic taking time off at the beginning, but not impossible.

For all the reasons pointed out by DeeAnn, I too like:
Research Alliance for Bat-borne Emerging Zoonoses
(RABEZ)

Best wishes
Tigga

Subject: Re: GBA Products and Action Items

Hi Katie et al.,

I too strongly support the January meeting for the reasons that Jon outlined and also because my teaching is in the fall semester and it would be hard for me to attend the meeting in Doha.

I support Jon's RABEZ suggestion. In reference to our colleagues in bat conservation, we need to have the pathogen component in the title. And, we can't, from a grammatical perspective be an alliance FOR bat pathogens, rather an alliance for the study of bat pathogens.

Thanks, DeeAnn

Subject: Re: GBA Products and Action Items

Hi Katie,
I propose meeting at the Prince Mahidol Award Conference (PMAC) in Bangkok, late January 2018. Primarily, I think November might be slightly early for our next meeting, given that we're working through governance and committee population. Also, PMAC is a big One Health meeting that at least three of us on the steering committee will already be attending, so there's some efficiency to it in terms of scheduling and expense, as well as having thematic relevance to our group.

Potential names:
1) Bat Ecology Research Network (BERN)

2) Bat Research Coordination Network (BRCN)

3) Global Alliance for Bat Research (GABR)

4) Research Alliance for Bat-borne Emerging Zoonoses (RABEZ)

Cheers,
Jon

Subject: Re: GBA Products and Action Items

Dear Katie,

Thanks for your message. The system failed to create an APAN account for me, will try other way. However, I would like to response to the 2 points. My suggestions are:

a. Next meeting during International Congress on Pathogens at the Human and Animal Interface (ICOPHAI) 7-9 November 2017, Doha, Qatar https://icophai.org/
b. Network name: Global Alliance for Bat-borne Pathogens (GABP)

kind regards

Subject: Re: GBA Steering Committee Planning Call
Attachment(s): "TORFTA_GBA_v7.docx","GBA Meeting Overview_29June2017.docx"

All,

This is a friendly reminder that we will be having the next planning call for the GBA Steering Committee tomorrow, Wednesday, 7 June at 0900 U.S. EST. The attached draft TORFTA and 29 June Fort Collins meeting agenda are attached for your reference (these were included on the Letter of Invitation emails that went out yesterday as well). Please review these documents, as we will be discussing them during the call.

Looking forward to speaking with you all tomorrow!

v/r,
Caitlin Devaney

From: caitlin.devaney
When: 9:00 AM - 10:00 AM June 7, 2017
Subject: GBA Steering Committee Planning Call
Location: Teleconference

All,

Please see below dial-in information for our next planning call scheduled for 7 June, at 0900 U.S. EST:

U.S. Dial-in: 1-703-552-8058

Singapore Dial-in: 65-3-1591097

Conference Code: 484877

(Alternative for Singapore callers) International Toll Free Dial-in: 800-492-2224

Call Agenda:

1. Brief Introductions
2. Review TORFTA feedback
    a. Discuss scope of the GBA steering committee membership
    b. Discuss organizational structure of the GBA steering committee
    c. Discuss roles and responsibilities of GBA steering committee membership
3. Discuss 29 June Fort Collins meeting
    a. Confirm attendance for 29 June meeting in Fort Collins
    b. Review meeting objectives
    c. Review meeting agenda
    d. Review proposed focus areas
4. Review action items (if any)

v/r,

Caitlin Devaney

Global Bat Alliance Meeting

Overview (objectives, agenda, and logistics)
29 June 2017

Meeting objectives (proposed)

1. Finalize GBA Terms of Reference for Trusted Agents (TORFTA)
2. Identify bat research focus areas and associated mentorship leads for each area
3. Prioritize research needs and gaps for each focus area and identify correlating researchers, institutions, other networks / alliances, and funding entities
4. Draft short and long-term timelines and workplans for each focus area
5. Determine steering committee convening schedule and Cohort II / III / IV training schedule

Focus areas (proposed)

- Virus / host relationship
- Commodity chain and trade routes
- Ecological change and effects
- Bat, livestock, and wildlife interactions

Note: these focus areas are not regionally based as previously discussed, in an effort to build towards the overarching objective of a multi-regional, multi-disciplinary network; they will be the subject of discussion during the 7 June virtual meeting and the 29 June GBA Meeting in Fort Collins

Logistics needs (proposed)

- Room for 25 with "U"-shaped set-up
- Projection capability
- Microphones (depending on #s)
- Catered lunch (working lunch w/ presentations)
- Name / organization table tents

Agenda

Time	Agenda Topic and Facilitator or Speaker	Expected Outcomes
0930 –	**Welcome and**	

1000	**Introductions**	
1000 – 1015	**Global Bat Alliance Overview** *Dr. Mary Lancaster (Africa Science Lead)* *Dr. Marty Stokes (SEA Science Lead, CBEP)*	• Review discussions leading up to this meeting • Discuss how this meeting is an opportunity to formalize the central / steering committee node for the distributed network • Emphasize that the steering committee shall focus on mentorship and connecting individuals and institutions across the globe
1015 – 1045	**Review Charter and Move to Agreement** *TBD*	• Vote to accept organizational document for steering committee • Unanimous (??) acceptance • We will advertise intent ahead of meeting • We will convene a meeting on 7 June to review and discuss the draft TORFTA
1045 – 1115	**Identify and discuss research focus areas** *TBD*	• Group will identify and discuss overarching focus areas and sub focus areas • Steering committee and invitees shall self nominate to groups and agree to serve as research mentors for the groups
1115 – 1230	**Breakout: Prioritize research needs and gaps** *TBD*	• Group will breakout into their research focus areas and begin identifying needs and gaps • Groups will then work to prioritize their lists
1230 – 1330	**Working Lunch** *TBD*	• Buffett • Convene back as a group, hold discussions about the overarching objectives of the alliance • Discuss One Health and Vector-based International meetings as an opportunity to re-convene semi-annually
1330 – 1400	**Breakout: Draft timelines and workplans** *TBD*	• Begin drafting short and long-term timelines and workplans for each focus area • Short-term milestones could include identifying key researchers and networks • Long-term milestones could include training events and focus area meetings
1400 – 1430	**Closing / review of actions** *TBD*	• Close-out meeting / 5min brief out for each group (2 slides) • Review action items and next steps

PROPOSED TERMS OF REFERENCE FOR TRUSTED AGENTS OF THE GLOBAL BAT ALLIANCE

1. BACKGROUND

The Global Bat Alliance (GBA) will serve as a platform to identify and connect interdisciplinary expertise to address challenges and threats posed by bat-associated pathogens of security concern. Specifically, the GBA shall convene a body of experts and researchers to: (1) share information, data, samples, and protocols; (2) coordinate research activities; (3) build training events and awareness-building workshops at all levels of decision-making authority; (4) develop community standards and best research practices; (5) create mentorship-based opportunities for students, trainees, and early-career researchers to convene, present, and share ideas; and (6) establish a community of international research leaders and champions.

Some of the world's most deadly emerging zoonotic diseases are found in bats, including Nipah, Hendra, and Marburg viruses. There are a number of factors which make bats unique disease reservoirs, including their social behavior and mutual grooming patterns, ability to travel long distances, nocturnal activity, species diversity, and long life span (10-20 years, compared with a rat's average life of two years).[1] These characteristics make bats very difficult to study within traditional controlled laboratory settings and create research challenges to understanding their roles in the global zoonotic disease ecology. The GBA will create opportunities for policy makers, researchers, funders, and students to identify research challenges, develop priority lists and associated action plans to target needs and gaps, and work at all levels to build awareness of bat-associated disease burden and transmission risks to improve the prevention, detection, diagnosis, and reporting of pathogens of security concern.[2]

2. GBA MISSION AND VISION

The GBA shall bring together scientists, policy makers, and medical/veterinary practitioners with interests in bat-related research involving pathogens of security concern. The network will build on community standards and best practices for research. The GBA will identify and share information on research funding opportunities offered by multiple institutions. Most importantly, the alliance will foster international relationships among collaborators, agencies, and organizations, which can produce long-term, sustainable partnerships that withstand changes in government and organization budgets, priorities, postures, and policies.

The Trusted Agents of the alliance with play a role in operationalizing the GBA, strengthening the linkages and reducing overlap in the global research effort on high-priority diseases of bats (especially

[2] Schountz, Tony, "Immunology of Bats and Their Viruses; Challenges and Opportunities," *Viruses,* 2014 Dec; 6(12): 4880-4901. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4276934/

zoonoses) to maximize the efficient use of expertise and resources and accelerate the coordinated development of disease surveillance and control methods.

3. OBJECTIVES

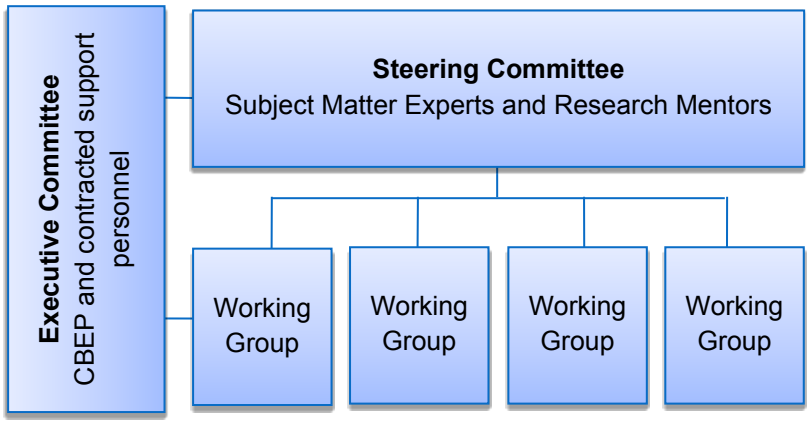
The objectives of the GBA are as follows:

- Facilitate interdisciplinary collaboration to identify research goals and needs for bat-associated disease research and disease threat reduction; and
- Unify CBEP regions to create a common action plan that yields collaborative projects that achieve the following end states: (1) better informed policy-makers; (2) better informed scientific community regarding funding targets and gaps in areas of research and development; and (3) better defined threat to global health security from bat-associated pathogens

4. APPROACH

The Terms of Reference for Trusted Agents (TORFTA) will convene subject matter experts to serve as mentors and function as independent, trusted advisors and honest brokers for research within the GBA. Trusted Agents will function within an organizational structure that consists of an Executive Committee, a Steering Committee, and four subject matter focused Working Groups.

4.1 The **Executive Committee (EC)** will be chaired by the CBEP Science Leads from Africa and Southeast Asia with organizational and administrative support from designated contractors for the program. The EC shall be responsible for developing GBA governance policies and guidelines, which could include coordinated research funding and approving invitations to serve on the Steering Committee and within the Working Groups. The EC and their team shall additionally be responsible for the following tasks (at a minimum):



- Establish broad objectives and goals for the GBA
- Organize and facilitate meetings for the GBA
- Provide secretarial support for all virtual and in-person meeting for the GBA
- Prepare materials on request
- Disseminate information including (but not limited to) newsletters, website links, press releases, meetings and conferences
- Coordinate with other funding agencies and organizations

4.2 The **Steering Committee (SC)** shall include scientific experts that shall act as the scientific coordinating body for global bat research, provide research gap analysis, and priority setting to the EC, as well as considering the scientific merit of proposals from the EC and assist with their implementation as per the terms of reference. To that end, the SC shall be responsible for the following items (at a minimum):

- Act as a scientific coordinating body for the GBA
- Consider the scientific merit of proposals from the EC
- Serve as subject matter experts and research mentors for implementation of accepted GBA-endorsed projects
- Propose research priorities
- Review and make recommendations on any matter involving an alteration in the mandate, terms of reference, membership, or structure of the GBA
- Review, discuss, and make recommendations for the logistics requirements of the GBA, sources and means of political and financial support, and its capability to function correctly in the future
- Define missions and submissions of the Working Groups, as well as identifying need for proposing establishment of new or closing-out existing WGs
- Supporting WGs in organizing gap analyses and research prioritization
- Promote interactions between WGs
- Assess and report progress of the WGs to other members of the SC and EC
- Develop and encourage exchange of protocols and best practices, and agree on standard operating procedures, good research practice, and roadmap to reach GBA goals (short and long-term)

4.2.1 Participate in semi-annual meetings. Meetings will normally take place twice annually in a place and at a time that is convenient for participants to a bat-relevant conference or meeting. The Chair may convene meetings at other times when they find support of at least two thirds of the members of the Steering Committee. These meetings can be virtual or in-person. The Secretary is responsible for ensuring that the agenda of the meeting is made available to the members in good time before the meeting.

4.2.2 Develop recommendations. Business will be conducted by careful and considered deliberation leading to recommendations to the GBA. Recommendations shall be decided by consensus where possible. Consensus means that after deliberation all members support a particular point of view. Where consensus is not achieved, recommendations shall be decided by simple majority vote of members voting on the question. In the case of a tied vote, the person acting as Chair shall be entitled to a second or deciding vote.

4.2.3 Attain consensus. A quorum is constituted by half of the number of individuals composing the Steering Committee rounded up when the number in the Steering Committee is uneven. The Steering Committee may decide by consensus or majority vote to ask parties who are not members of the Steering Committee to participate in a meeting so that they can provide relevant information, material, or knowledge. The Steering Committee may establish sub-committees consisting of 3 or more of its members and refer to them any matter in the Steering Committee's mandate. It may co-opt other GBA participants onto such committees.

4.3 The **Working Groups (WG)** shall serve to divide the GBA into multi-disciplinary, multi-national focus areas to meet the research challenges associated with bat-borne diseases. Members of the SC shall serve as research mentors and subject matter experts within each WG. The WGs will focus on the following focus areas (*please note, these focus areas are very much in draft form and will be the subject of discussion during the 7 June virtual meeting and the 29 June GBA Meeting in Fort Collins)*:

- Virus / host relationship
- Commodity chain and trade routes
- Ecological change and effects
- Bat, livestock, and wildlife interactions

5. GOVERNANCE AND MEMBERSHIP

5.1 Accountability

The overarching duty of the GBA is to develop multi-disciplinary and multi-national hypothesis driven research projects that meet the prioritized challenges defined by the Executive Committee under advice from the Steering Committee. Accountabilities of the GBA EC, SC, and Members include the following:

- Each member shall be familiar with the TORFTA and the mandate of the committees or WGs on which they serve
- Each member shall promote a culture of responsible practice for scientific research
- Each member shall work towards the short- and long-term goals of the GBA with a particular emphasis on the foci that fall within their WG
- Members of the SC are selected for their breadth of experience, insight and knowledge, integrity and character, and sound and independent judgment. Therefore, they are expected to bring these personal qualities to their role on the SC and apply impartial judgment to help the EC make informed and independent decisions

5.2 Conflicts of Interest

This terms of reference document adopts a modified National Academy of Sciences (NAS) definition of Conflict of Interest: a conflict of interest in research exists when the individual has interests in the outcome of the research that may lead to a personal, institutional, or financial advantage and that might therefore, in actuality or appearance compromise the integrity of the research."

No member of the Steering Committee may participate in a discussion where such participation would give rise to a potential conflict of interest. SC members must recuse themselves if such a conflict is perceived. The EC will review all situations where potential personal, institutional, or financial conflicts of interest are suspected.

SC members may leave their term of service on the SC if they wish to participate in a funding opportunity that would otherwise be perceived as a conflict of interest.

5.3 Selecting Committee Members

The SC and members of the WGs shall include members that reflect the multi-disciplinary and multi-national nature of the GBA. There are no term limits for members of the GBA, who are allowed to

participate at will in accordance with terms of the TORFTA. However, members of the SC follow other rules for selection:

- ***5.3.1*** ***Terms of service –*** *2 years, no term limit*
- ***5.3.2*** ***Eligibility*** *– representation from each CBEP region must be maintained*
- ***5.3.3*** ***Nomination process –*** *nominated at the end of even calendar years by peers (members of the GBA) at GBA research review meetings or electronically*
- ***5.3.4*** ***Selection process –*** *reviewed by members of the EC under advisement of the SC*

Members of the WGs will not follow any rules for selection other than representing CBEP regions. There will be no term limits, WG members are encouraged to contribute and participate indefinitely. Members shall be nominated and invited to participate by members of the EC and SC.

Subject: Re: GBA Steering Committee Planning Call

All,

This is a friendly reminder that we will be having the next planning call for the GBA Steering Committee tomorrow, Wednesday, 7 June at 0900 U.S. EST. The attached draft TORFTA and 29 June Fort Collins meeting agenda are attached for your reference (these were included on the Letter of Invitation emails that went out yesterday as well). Please review these documents, as we will be discussing them during the call.

Looking forward to speaking with you all tomorrow!

v/r,
Caitlin Devaney

From: caitlin.devaney
When: 9:00 AM - 10:00 AM June 7, 2017
Subject: GBA Steering Committee Planning Call
Location: Teleconference

All,

Please see below dial-in information for our next planning call scheduled for 7 June, at 0900 U.S. EST:

U.S. Dial-in: 1-703-552-8058

Singapore Dial-in: 65-3-1591097

Conference Code: 484877

(Alternative for Singapore callers) International Toll Free Dial-in: 800-492-2224

Call Agenda:

1. Brief Introductions

2. Review TORFTA feedback

    a. Discuss scope of the GBA steering committee membership

    b. Discuss organizational structure of the GBA steering committee

    c. Discuss roles and responsibilities of GBA steering committee membership

3. Discuss 29 June Fort Collins meeting

    a. Confirm attendance for 29 June meeting in Fort Collins

    b. Review meeting objectives

    c. Review meeting agenda

    d. Review proposed focus areas

4. Review action items (if any)

v/r,

Caitlin Devaney

Global Bat Alliance Steering Committee | Planning Meeting Notes
0900 US EST 7 JUNE 2017

ATTENDEES

- Dr. Marty Stokes (CBEP)
- Dr. Mary Lancaster (CBEP)
- MAJ Omar Gamboa (CBEP)
- Dr. Will Sander (CTR A&AS Booz Allen)
- Ms. Katie Leahy (Global Systems Engineering)
- Ms. Caitlin Devaney (Global Systems Engineering)
- Ms. Mary Dugan (Global Systems Engineering)
- Dr. Vivek Kapur (Penn State University)
- Dr. Jon Epstein (EcoHealth Alliance)
- Dr. Kevin Olival (EcoHealth Alliance)
- Dr. Joram Buza (NM-AIST)
- Dr. Rebekah Kading (Colorado State University)

ACTION ITEMS

Task	Responsible	Due Date
Send GBA research database to the group	Global Systems Engineering	14 JUNE
Add to GBA research database	ALL	Rolling; ~29 June meeting
Update TORFTA and send to the group	Global Systems Engineering	14 JUNE
CBEP to work with Dr. Kading on additional participants and logistics requirements	CBEP	Rolling

AGENDA

TORFTA feedback and discussion

- **Discussion was opened for comments and suggestions for TORFTA revisions**
  - The intent was to build toward consensus on a near-final document, so that the TORFTA can be finalized during the 29 June meeting in Fort Collins.
- **TORFTA concept and framework**
  - Trusted agents are individuals who act in the best interest, and as an extension, of the sponsor organization. In the case of the GBA steering committee, these trusted agents would become an extension of CBEP. They also deal with conflicts of interest with the intent to only better the organization.
  - The basic framework of the TORFTA consists of the steering committee and working groups, which report out to the executive committee. This hierarchy is very useful when large amounts of information are discussed / priorities within the alliance need to be established. The general structure has been proven to be effective in several other domestic and global alliances.
  - It will be important to first define the functions of the GBA, and the working groups, and to then build a complimentary and supportive organizational structure.
  - More information on the scope of the steering committee, and the steering committee selection process is needed.
    - Invitations to join the steering committee have been extended to individuals in PACOM, EUCOM, AFRICOM, CENTCOM, and the conservation field. In total 17 individuals are accounted for currently.
- **Resolution for potential conflict of interest issues**
  - The question of how subject matter experts with current / future work in the field can resolve any conflict of interest that could come with steering committee membership (advising, shaping, and mentoring while staying involved in research / fieldwork) was raised.
  - One of CBEP's biggest concerns is to ensure future projects and research are not precluded for steering committee members.

- Assigning mentors for each working group, who are not on the Steering Committee, could mitigate some of the conflict of interests.
- A system of checks and balances must be in place to account for possible overlap with facilitation of research.
- An alternative approach could be using a request for information/assessment which would draw interested parties together to form a research consortia. This way they can directly address the objectives, while still being able to award multiple lines of effort.
- It should be explicitly stated that the executive committee makes funding decisions, which is separate from the steering committee.
- Include definitions of funding selection criteria; and methods to support and relieve established researchers.
- Section 5.2 “Conflicts of Interest” must be clarified and strengthened in the TORFTA in order to highlight above discussion.

- **Roles and Responsibilities**
  - The last sentence of the TORFTA was discussed. It was noted that the steering committee will nominate members for the GBA, but that further clarification of rules and responsibilities of steering committee members must be defined. Mutual trust and shared philosophy is crucial in the membership process and for future growth and healthy agreements within the alliance.
  - Section 4.2 mentions the Chair position, a role that needs to be explicitly defined.
  - Section 4.3 regarding working groups needs to be built out further.

Discussion about the 29 June Fort Collins meeting

- The proposed GBA focus areas will be reviewed during the Fort Collins meeting.
  - Mentors for working groups will be identified, along with the structure of the working groups.
- All agreed that the proposed objectives and agenda for the meeting are satisfactory.
- The prioritization of the needs and gaps within research areas will be an ongoing process (it will take longer than the meeting itself).

Subject: GBA Update and Request

All,

On behalf of Dr. Mary Lancaster and Dr. Marty Stokes, we would like to thank everyone, for your responses over the last couple weeks! Based on your feedback, we have a few announcements and one request:

Based on committee consensus, the group chose our next event to coincide with the Participatory Epidemiology Network for Animal and Public Health (PENAPH) on 10-12 January 2018, in Khon Kaen, Thailand. Details will be forthcoming, but please visit the hyperlink for further information (https://penaph.net/second-penaph-conference-participatory-approaches-in-animal-health-public-health-one-health-and-ecohealth/).

We did not receive additional nominations to serve as co-chairs, so we are pleased to announce our first Steering Committee Co-chairs: Dr. Jon Epstein from EcoHealth Alliance and Dr. Vivek Kapur from Penn State University. We will be setting up coordination calls with our two co-chairs, so you can expect communication and direction from them in the future.

Finally, one request; we did not have a majority vote selection for our organization's name, which leaves us with two options:

Option 1 Bat-associated Pathogen and Ecology Research Network (BPERN) and

Option 2 Global Alliance for Bat-borne Pathogens (GABP).

Please respond to this email with your selection no later than 24 August. We will tally the votes and make an announcement thereafter.

Thank you, again, for signing up to the APAN site and being so responsive to the request. We will be loading the first documents and drafts to the site (e.g., the TORFTA and community fact sheet) in the next couple weeks. You may expect email from us with information concerning our next meeting in January and planning discussions leading up to that meeting.

Subject: Re: Meeting request: Global Bat Alliance Network (convened on behalf of CBEP)

Dear Katie,

Glad to receive yours. Thanks very much. Unfortunately i shall be in the field in a remote part of Uganda starting on the 14th-May-2017. Most of the day i shall not have access to connectivity, how ever please send the invitation to call in. If i happen to be at the hotel at that time, i will certainly join into the discussion. I will in the meantime look through the document that you attached.

Best regards

Dear Dr. Olival,
We are pleased to inform you that your manuscript 'Title - Possibility for reverse zoonotic transmission of SARS-CoV-2 to free-ranging wildlife: a case study of bats

Short Title - Possibility for SARS-CoV-2 transmission from humans to free-ranging bats' has been provisionally accepted for publication in PLOS Pathogens.
Before your manuscript can be formally accepted you will need to complete some formatting changes, which you will receive in a follow up email. A member of our team will be in touch with a set of requests.
Please note that your manuscript will not be scheduled for publication until you have made the required changes, so a swift response is appreciated.
IMPORTANT: The editorial review process is now complete. PLOS will only permit corrections to spelling, formatting or significant scientific errors from this point onwards. Requests for major changes, or any which affect the scientific understanding of your work, will cause delays to the publication date of your manuscript.
Should you, your institution's press office or the journal office choose to press release your paper, you will automatically be opted out of early publication. We ask that you notify us now if you or your institution is planning to press release the article. All press must be co-ordinated with PLOS.
Thank you again for supporting Open Access publishing; we are looking forward to publishing your work in PLOS Pathogens.

Subject: Paper Proof - please review. "Title - Possibility for reverse zoonotic transmission of SARS-CoV-2 to free-ranging wildlife: a case study of bats Short Title - Possibility for SARS-CoV-2 transmission from humans to free-ranging bats" (PPA...

Dear all,

The attached typeset proof of our paper just arrived, and I have two days to reply.*Acceptable corrections are limited to author name or affiliation errors, misleading scientific inaccuracies, and printer's errors.* Change requests beyond these items will not be accepted.

Please quickly double check your name and affiliation, and if you find any errors please let me know by COB tomorrow. If I don't hear back, I'll assume it is correct.

Our article currently has a provisional scheduled publication date of Sep 03, 2020. Please note that our paper will**remain under a strict press embargo** until 2 PM Eastern Time (US) on the date of publication, so please don't circulate or tweet! :)

Thanks!
Kevin

Attachment(s): "Infographic and acknowledgement.docx"

Dear Tigga and Rodrigo,
Attached is the figure with the acknowledgment. The WHSG would prefer not to include logos on the figure if possible as it is positioned in the middle of our text. However, I want to ensure you are satisfied with it. So if you have any concerns about the acknowledgement, please let me know by Thursday Aug 20.

Thanks very much!

And thanks again to you and Rebekah for letting us modify your great figure:)

Best,

Mindy

Hi Mindy, Billy, Kevin, and Kendra -

I hope your week has gotten off to a good start!

I'm attaching a draft infographic for your review. I've modified the current BSG MAP infographic per your suggestions for a wildlife version. I can also add a logo, QR, and/or website at the bottom if you'd like. Not sure of exactly the best way to portray environmental samples...I was assuming this will comprise activities like passive fecal sample collections...so please let me know if this captures what you had in mind or if there is something else you're envisioning and I can revise accordingly! (BioRender does have an amusing variety of poo icons, but I was trying to keep it classy and professional.) ��

Take care, and I'll look forward to your feedback.

Best,
Rebekah

Subject: Re: Preventing human-to-bat transmission of SARS-CoV-2 Figure

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change

the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Dear Rebekah,

This looks awesome!! I shared it this evening with our small team that is preparing the guidelines for the rest of the specialist group to review and they like it very much (that's a great ferret:)! We are going to share the guidelines tomorrow with a larger team in the specialist group for the final review so this is perfect timing.

I will also find out about branding from the WHSG and will get back to you on that. I also want to make sure we also give credit your specialist group. Tigga and Rodrigo, as I mentioned we will include a statement that this is modified from the BSG's figure. Please advise on any other branding requirements.

Thanks very much!!

I just wanted to let you know that I've sent this to 2 email addresses for Rodrigo and it seems they have bounced back. I am not sure if he has seen my request.

I hope to hear from you soon about whether the Wildlife Health Specialist Group can use or modify your infographic (with the appropriate credit).

Best,
Mindy

Hi Rebekah and all.

Thanks again for the graphic.

OIE is distributing our joint WHSG/OIE guidelines and also translating it to French and Spanish as they normally do. They would like to change the language in the graphic also but need either the editable file or at least the background images on which they can overlay the French and Spanish. Are either of those something you could provide?

Thanks,

Billy

Hi everyone -

So sorry for the delay! I'm attaching the Infographic -- a pdf version with clickable links and a png version which may be easier for social media postings. Just let me know if you have any final suggestions. We are very happy to collaborate with you on aligning the messaging coming from our working groups on this issue - thank you again very much for reaching out about this!

Kind regards,
Rebekah

Dear Tigga and Rodrigo,
Attached is the figure with the acknowledgment. The WHSG would prefer not to include logos on the figure if possible as it is positioned in the middle of our text. However, I want to ensure you are satisfied with it. So if you have any concerns about the acknowledgement, please let me know by Thursday Aug 20.

Thanks very much!

And thanks again to you and Rebekah for letting us modify your great figure:)

Hi Mindy, Billy, Kevin, and Kendra -

I hope your week has gotten off to a good start!

I'm attaching a draft infographic for your review. I've modified the current BSG MAP infographic per your suggestions for a wildlife version. I can also add a logo, QR, and/or website at the bottom if you'd like. Not sure of exactly the best way to portray environmental samples...I was assuming this will comprise activities like passive fecal sample collections...so please let me know if this captures what you had in mind or if there is something else you're envisioning and I can revise accordingly! (BioRender does have an amusing variety of poo icons, but I was trying to keep it classy and professional.) ��

Take care, and I'll look forward to your feedback.

Best,
Rebekah

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Dear Tigga and Rodrigo,
Attached is the figure with the acknowledgment. The WHSG would prefer not to include logos on the figure if possible as it is positioned in the middle of our text. However, I want to ensure you are satisfied with it. So if you have any concerns about the acknowledgement, please let me know by Thursday Aug 20.

Thanks very much!

And thanks again to you and Rebekah for letting us modify your great figure:)

Hi Mindy, Billy, Kevin, and Kendra -

I hope your week has gotten off to a good start!

I'm attaching a draft infographic for your review. I've modified the current BSG MAP infographic per your suggestions for a wildlife version. I can also add a logo, QR, and/or website at the bottom if you'd like. Not sure of exactly the best way to portray environmental samples...I was assuming this will comprise activities like passive fecal sample collections...so please let me know if this captures what you had in mind or if there is something else you're envisioning and I can revise accordingly! (BioRender does have an amusing variety of poo icons, but I was trying to keep it classy and professional.) ��

Take care, and I'll look forward to your feedback.

Best,
Rebekah

Subject: Re: Preventing human-to-bat transmission of SARS-CoV-2 Figure

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change “bats” to either “mammals” or “wild mammals”, change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from “i.e. implement acoustic surveys” to “i.e. collect environmental samples”, and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn’t need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Dear Mindy

The infographic was constructed in BioRender by Dr Rebekah Kading, so they would probably need to be manipulated in that environment. I've copied Rebekah and Dr Bella Mandl – who is also leading our graphics – on this email.

They have also worked up infographics for rehabbers and cavers and the original is now in a number of languages. Rebekah is a whizz at adapting the base design, but we of course need to be mindful of her time.

Critically, we would need to review and sanction any changes because we don't want any messages to conflict with our own. It would be confusing to have essentially the same graphic circulating saying different things. Our messaging is organized around the MAP concept so we don't want that disrupted, for example.

Do you have a clearer idea of how you would use the infographic?

Caveats aside, happy to work with you of course!!

Best wishes
Tigga

P.S. I copied Rodrigo with his current email.

Dear Tigga,
I just wanted to let you know that I've sent this to 2 email addresses for Rodrigo and it seems they have bounced back. I am not sure if he has seen my request.

I hope to hear from you soon about whether the Wildlife Health Specialist Group can use or modify your infographic (with the appropriate credit).

Best,
Mindy

We thought that the documents that the Bat Specialist Group wrote were great and we certainly refer anyone working with bats to review your guidelines as well.

We really liked the figure you used (pasted below) and were wondering if we could reproduce it and/or modify it slightly in our document. We would certainly credit your group with creating it.

If it is ok to modify it, would it be possible to get a powerpoint slide or photoshop document to allow for easy modification?

I look forward to hearing from you and we would be happy to promote your work.

Kind regards,

Mindy

Hi everyone

Thank you Tigga for copying me with the good email address. Mindy good talking to you again. I fully concur with Tigga about being mindful of the brains behind the infographic, and of course about any changes. If at all possible Mindy we would rather have it presented with due credits verbatim. Multiple version will be confusing, regardless of whether the different versions clash with each other. Stay safe.

Thank you Rodrigo and Tigga for your thoughtful responses.

I am going to take your response back to our group. We will see if we can make it work without changes and if not come back to you with as few changes as we think would be necessary (e.g. changing “bats” to “mammals”, etc.) and see if you think the changes are minimal enough that it still provides the same strong message. We do like your message and that was part of the reason why we wanted to use the figure:)

Hi Billy,

The pdf version should be editable, so they should be able to work directly on that and then re-save as an image file. As an alternative, if anyone in your working group or OIE has a BioRender license, I can share the infographic file directly with that person through BioRender to edit. Third option - I'm attaching a translation sheet that could be used as a template. It still has the bat infographic language on it, but if this is updated with the French and Spanish translations for the wildlife infographic, feel free to send those translations back to me and I'd be happy to update the infographic.

Hope that helps, and just let me know how you'd like to proceed.

Hi Rebekah and all.

Thanks again for the graphic.

OIE is distributing our joint WHSG/OIE guidelines and also translating it to French and Spanish as they normally do. They would like to change the language in the graphic also but need either the editable file or at least the background images on which they can overlay the French and Spanish. Are either of those something you could provide?

Thanks,

Dear Tigga and Rodrigo,
Attached is the figure with the acknowledgment. The WHSG would prefer not to include logos on the figure if possible as it is positioned in the middle of our text. However, I want to ensure you are satisfied with it. So if you have any concerns about the acknowledgement, please let me know by Thursday Aug 20.

Thanks very much!

And thanks again to you and Rebekah for letting us modify your great figure:)

Hi everyone

Thank you Tigga for copying me with the good email address. Mindy good talking to you again. I fully concur with Tigga about being mindful of the brains behind the infographic, and of course about any changes. If at all possible Mindy we would rather have it presented with due credits verbatim. Multiple version will be confusing, regardless of whether the different versions clash with each other. Stay safe.

Dear Rodrigo and Tigga,

Rodrigo, it's been several years since we have spoken and I hope you are well.
I hope you are both managing to stay safe during the pandemic.

I have been working with Billy Karesh, some folks from the Wildlife Health Specialist Group and the OIE to come up with some recommendations for working with free-living, wild mammals during the pandemic. We thought that the documents that the Bat Specialist Group wrote were great and we certainly refer anyone working with bats to review your guidelines as well.

We really liked the figure you used (pasted below) and were wondering if we could reproduce it and/or modify it slightly in our document. We would certainly credit your group with creating it.

If it is ok to modify it, would it be possible to get a powerpoint slide or photoshop document to allow for easy modification?

I look forward to hearing from you and we would be happy to promote your work.

Kind regards,

Mindy

Hi Rebekah,

Wow, that is amazing! The environmental sampling icons are perfect!

I was checking into BioRender today to make a schematic for a publication, do you use the free version?

Cheers,
Kendra

P.S. Fingers and toes crossed for Anna's interview with EHA this Friday:)

I can also add a logo, QR, and/or website at the bottom if you'd like. Not sure of exactly the best way to portray environmental samples...I was assuming this will comprise activities like passive fecal sample collections...so please let me know if this captures what you had in mind or if there is something else you're envisioning and I can revise accordingly! (BioRender does have an amusing variety of poo icons, but I was trying to keep it classy and professional.) ��

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Dear Aleksei, Peter, and Hongying,

I enthusiastically recommend Dr. Anna Fagre for the Research Scientist and Project Manager position at EcoHealth Alliance.

To speak to Anna's **research experience and capability**: I've known Anna since I joined the CSU faculty in 2016, when she arranged to a rotation as part of her microbiology residency. Anna formally joined my laboratory as a PhD student in July 2017. Her dissertation is focused on the role of bats as reservoirs of emerging arboviruses, and she has made significant progress on both *in vitro* and *in vivo* studies involving bat-associated orbiviruses. The primary emphasis of these studies is on characterization of Bukakata orbivirus, a novel virus that I isolated from a fruit bat in Uganda in 2013. Bukakata orbivirus is putatively tick-borne, based on the phylogenetic analyses we have conducted. To study this virus in the broader context of other orbiviruses that have been isolated from naturally-infected bats, we acquired all three of the remaining bat-associated orbiviruses from the CDC reference collection as well as Chobar Gorge virus, a tick-borne orbivirus to which Bukakata appears to be closely related. Anna's molecular and phylogenetic characterization of Bukakata and other bat-associated orbiviruses was published in a special collection on bat viruses, in the journal Viruses (PMID: 30832334) along with a comprehensive review of the potential for bats to serve as reservoirs for arboviruses (PMID: 30832426). Since the time these papers were completed, Anna has also put significant effort into investigating the use of subgenomic RNA derived from the 3'UTR of flaviviruses to look for evidence of past infection in archived tissue samples. Because of the complex hairpin structure of the viral RNA in the 3'UTR, it is protected from RNA degradation by the exonuclease XRN1, so we hypothesized that we would find residual viral RNA that could be amplified and sequenced. After optimizing this methodology, Anna screened all of our remaining bat tissue samples from Uganda, going back 10 years, and discovered that 4 bats between 2009 – 2013 had been infected with Zika virus. Moreover, this Zika virus sequence was most similar to the Asian lineage, suggesting either diversification of Zika virus strains prior to the virus expanding into Asian in the ~1960s or spillback into Africa of the epidemic strain much earlier than we have appreciated. This manuscript is currently in review. All in all, Anna's work in my lab has been top-notch. She is meticulous and hard-working and has an excellent grasp of the molecular methodologies and big picture of how they can be applied innovatively in an ecological context. In each of these projects, she has done an excellent job leading, and taken initiatives beyond the original study scope that have made the work much stronger in the end. Her **background in veterinary medicine** has also added valuable perspective, and been very much in-demand as she has helped other laboratories on campus during this pandemic with *in vivo*studies involving SARS-CoV-2.

Other key attributes relevant to the current opportunity:

Anna is highly **collaborative,** personable, and very proactive in seeking these collaborations. This year she has re-connected with a former CSU graduate school colleague who is now in Bangladesh, and has been actively developing some research ideas and using her own funding to generate preliminary data. She also joined the VERENA consortium and has been working on a review paper with collaborators in that group. She works very well with others, as a leader of diverse teams as well as a contributing member. She has had the opportunity to contribute to a number of **international projects** both as part of my lab and during her previous experience, and is very adaptable, capable, and enthusiastic about working internationally. Over the past year she has been an invaluable member of an global initiative led by the CSU Office of the Vice President for Research, and has earned the respect of the highest CSU leadership for her contributions to this team.

Anna has been successful at **securing extramural funding**, of her own initiative. Since joining my lab, she has been awarded three highly-competitive fellowships and grants: An NIH TL1 fellowship through the Colorado Clinical and Translational Science Institute, a spot on the NIH T32 award to CSU, and the 2019 Robert E. Shope International Fellowship in Infectious Diseases through ASTMH/ACAV.

Anna is an excellent writer and **science communicator**, and also publishes frequently on blogs and other social media platforms in addition to her prolific peer-reviewed publications. She is the literature watchdog of the lab, and somehow seems to know about every relevant paper or report that is published within a half hour of it hitting the press. Anna has

excellent soft skills when interacting with other professionals. She was featured in a documentary video made by CSU, and had a very natural presence and ability to clearly explain her research and general principles of disease ecology in lay terms.

In conclusion, I give Anna my highest recommendation and think she would be a fantastic addition to your team. Anna is extremely proactive, self-motivated, skilled, and has brought a wonderful energy and work ethic to my laboratory. She is an up-and-coming leader in the field, and I am thrilled to have her as part of my team. This turned out to be not-so-brief a recommendation, but I hope was a useful assessment! If you have any questions or if I can be of any additional assistance, please do not hesitate to contact me.

Best regards,
Rebekah

Dear Dr. Kading,

We just interviewed Anna Fagre for a position here at EcoHealth Alliance as a Research Scientist and Project Manager. Our hiring committee thought she was terrific with the right background and attitude for our team. Anna listed you as a reference. If you would be willing to send some comments about Anna, that would be terrific!

I have attached our position advertisement, so you may know more about the position - though based on her skillset, the specifics would evolve a bit. This position would focus primarily on our emerging infectious disease projects based in Southeast Asia including our recently awarded, NIAID funded EID-SEARCH program:

- https://www.ecohealthalliance.org/program/south-east-asia-research-collaboration-hub

I look forward to your reply and should a phone call be more convenient, we could do that as well.

On behalf of our whole committee, I sincerely appreciate your time.

Subject: Reminder: BOHRN November IMED Meeting Invitation

All,

As a reminder, please respond NLT **14 September** if you are able to attend the BOHRN/IMED Meeting in Vienna on 8-12 November 2018. The BOHRN meeting will be held 8-9 November.

We are looking for nominations to grow the BOHRN network, please send any nominations of subject matter experts or other participants who would be beneficial to this discussion **no later than Today, 10 September 2018**.

IMED will take place 9 – 12 November at the Hilton Vienna. The 2018 IMED will focus on innovation and changes in political and societal responses to outbreaks. The theme of IMED aligns with our overall BOHRN objectives and we encourage all BOHRN members to stay and participant in the conference.

We need you to confirm your attendance to BOHRN and IMED NLT 14 September.

v/r,

Megan

Subject: BOHRN November IMED Meeting Invitation

All,

On behalf of Dr. Marty Stokes you are receiving this email, as part of a save the date to attend our BOHRN Steering Committee meeting and International Meeting on Emerging Diseases and Surveillance (IMED) 8 – 12 November 2018 in Vienna, Austria.

Our meeting will take place on 8 – 9 November (hotel/meeting location TBD). The BOHRN steering committee meeting will aim to meet the objectives the group identified in Saskatoon. The following objectives were suggested based on your survey responses:

1. Prioritizes funding needs based on working groups' characterization of gaps and needs, to help organize and develop funding initiatives; and
2. Analyze progress of action plans and their yields establishing collaborate and sustainable projects

To facilitate these objectives, we will be asking each working group to present their progress. The progress updates for each working group are imperative to the outcomes for this meeting.

As discussed during the June BOHRN meeting, an objective of this meeting is to develop our outreach and populate working groups. Please send any nominations of subject matter experts or other participants who would be beneficial to this discussion **no later than 10 September 2018**.

IMED will take place 9 – 12 November at the Hilton Vienna. The 2018 IMED will focus on innovation and changes in political and societal responses to outbreaks. The theme of IMED aligns with our overall BOHRN objectives and we encourage all BOHRN members to stay and participant in the conference. **Therefore, we need you to confirm your attendance to BOHRN and IMED NLT 14 September.**

CC: olival ecohealthalliance.org>
Subject: RE: SARS-CoV-2 spillback risk to North American bats

Hi Paul
Very interested to see the MS. Rebekah and I have been working on something that arose out of BOHRN that would be very complementary and might be worth trying to coordinate dissemination in some way. We are meeting today and will take stock of where we are at.

I just started an email to you and Kevin about the state of affairs as we Rodrigo and I are getting quite a bit of push-back on the IUCN BSG recommendation to suspend field studies while further data are gathered (primarily from western scientists with access to PPE). It would be good to hear what those committees are finding sooner rather than later.

Best wishes
Tigga

To: Kingston, Tigga < >
Cc: ecohealthalliance.org
Subject: SARS-CoV-2 spillback risk to North American bats

Hi Tigga,

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Hi Team,

Funny thing, bioRxiv actually rejected us! Apparently they don’t take “reviews”.

In any case we got **very positive reviews back from *PLoS Pathogens*** today, and the revised ms was just resubmitted (<24 hour turnaround). Woohooo! Finger’s crossed that the editors turn it around again quickly and we can see this published soon.

Attached is the cover letter, response to reviewers, and the resubmitted version of ms.

Cheers,
Kevin and Paul

Dear all,

We successfully submitted to bioRxiv yesterday and it's currently in "review" with the editorial staff and should be posted within 48 hours. Big thanks to Paul for getting the final USGS approvals and ms formatting in place.

Hume and Charlie, I understand your very valid and "traditional" concerns here, there's a lot of riff-raff out there on pre-print servers and hence why we have the peer-review system. Nonetheless, given that there are other similar reviews being posted at the moment and the timeliness of this given the USGS/USFW Risk Assessment out last week, etc., would be best to get this out there while we're still in review at PLOS.

Best,
Kevin

Dear all,

Update on our ms. It was submitted to PLOS Pathogens on June 2nd (you should have all received an email from the journal confirming this) and it is currently under review.

We are in the final stages of USGS approval to also submit to bioRxiv (pre-print server), and expect to finalize that and post it on bioRxiv in the next 24 hours. *Please let me know if there are any objections.*

Cheers,

Kevin

Dear Co-authors,

Attached is the latest, submission ready version of our paper "**Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats**". Thank you all for the last round of invaluable edits and comments. Paul and I have now gone through multiple revisions since you last saw the paper in an attempt to include everyone's feedback; so apologize for the delay in turning this around and moving towards submission.

We started a submission to *Lancet Infectious Diseases*, but after thinking more about the journal's scope and reading other recent reviews that have been published in the journal, Paul and I decided it was not the best fit after all. We instead plan to submit this as a Perspectives article to *PNAS*(https://www.pnas.org/page/authors/purpose-scope). We think *PNAS* is a better fit all around, especially given the US focus of our review. We are currently following up some leads for "sponsorship" of our paper with PNAS which would make it an invited piece. If you have any specific suggestions in this regard, please let me know.

As before, the plan is once we submit (hopefully this week) to *PNAS* we will also post as a pre-print on BioRxiv so it can be viewed and used immediately. **If there are any objections to this plan or to submit to *PNAS*, please let me know.**

Also, for those that have secured USG approval already, please let me know if these needs to be updated or if you need any more information.

This has been a fantastic exercise in group writing! Big thank you to everyone.

Cheers,

Kevin

Thanks all - I am in support of bioRxrv for this paper (although I don't systematically use it - in this fast moving CoV environment, for some papers I think it is a very good option).

Cheers - DeeAnn

Dear all,

Update on our ms. It was submitted to PLOS Pathogens on June 2nd (you should have all received an email from the journal confirming this) and it is currently under review.

We are in the final stages of USGS approval to also submit to bioRxiv (pre-print server), and expect to finalize that and post it on bioRxiv in the next 24 hours. *Please let me know if there are any objections.*

Cheers,

Kevin

Dear all,

We successfully submitted to bioRxiv yesterday and it's currently in "review" with the editorial staff and should be posted within 48 hours. Big thanks to Paul for getting the final USGS approvals and ms formatting in place.

Hume and Charlie, I understand your very valid and "traditional" concerns here, there's a lot of riff-raff out there on pre-print servers and hence why we have the peer-review system. Nonetheless, given that there are other similar reviews being posted at the moment and the timeliness of this given the USGS/USFW Risk Assessment out last week, etc., would be best to get this out there while we're still in review at PLOS.

Best,
Kevin

Thanks Peter, *EcoHealth* is a great back up option. PLOS Pathogens review editor seemed quite receptive to it (we heard back today), so we're going to submit there first and see. I'll get it back in this weekend.

Cheers,
Kevin

Subject: Re: SARS-CoV-2 spillover risk to North American bats manuscript - FINAL version for PLOS Pathogens (new plan)

Dear all,

We successfully submitted to bioRxiv yesterday and it's currently in "review" with the editorial staff and should be posted within 48 hours. Big thanks to Paul for getting the final USGS approvals and ms formatting in place.

Hume and Charlie, I understand your very valid and "traditional" concerns here, there's a lot of riff-raff out there on pre-print servers and hence why we have the peer-review system. Nonetheless, given that there are other similar reviews being posted at the moment and the timeliness of this given the USGS/USFW Risk Assessment out last week, etc., would be best to get this out there while we're still in review at PLOS.

Best,
Kevin

Dear all,

Update on our ms. It was submitted to PLOS Pathogens on June 2nd (you should have all received an email from the journal confirming this) and it is currently under review.

We are in the final stages of USGS approval to also submit to bioRxiv (pre-print server), and expect to finalize that and post it on bioRxiv in the next 24 hours. *Please let me know if there are any objections.*

Cheers,

Kevin

Dear Co-authors,

Attached is the latest, submission ready version of our paper "**Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats**". Thank you all for the last round of invaluable edits and comments. Paul and I have now

gone through multiple revisions since you last saw the paper in an attempt to include everyone's feedback; so apologize for the delay in turning this around and moving towards submission.

We started a submission to *Lancet Infectious Diseases*, but after thinking more about the journal's scope and reading other recent reviews that have been published in the journal, Paul and I decided it was not the best fit after all. We instead plan to submit this as a Perspectives article to *PNAS*(https://www.pnas.org/page/authors/purpose-scope). We think *PNAS* is a better fit all around, especially given the US focus of our review. We are currently following up some leads for "sponsorship" of our paper with PNAS which would make it an invited piece. If you have any specific suggestions in this regard, please let me know.

As before, the plan is once we submit (hopefully this week) to *PNAS* we will also post as a pre-print on BioRxiv so it can be viewed and used immediately. **If there are any objections to this plan or to submit to *PNAS*, please let me know.**

Also, for those that have secured USG approval already, please let me know if these needs to be updated or if you need any more information.

This has been a fantastic exercise in group writing! Big thank you to everyone.

Cheers,

Kevin

Hi Folks,

Quick update on our paper — unfortunately got news yesterday that *PNAS* was not interested in this as a Perspectives piece, and rejected our proposal. We are currently pursuing options with editors at *PLOS Pathogens* to see if they want it as a review. Will keep you all posted.

Latest version attached that has cleared CDC and USGS review. We will still aim to get this on BioRxiv, but wanted to wait until we had it cleared first and ideally in review at a journal.

Thanks Kevin. Totally agree it's important to get it out as a pre-print in terms of timely accessibility. I was just taking the opportunity to reflect more broadly!

Look forward to promoting it on Twitter.

Hi Team,

Funny thing, bioRxiv actually rejected us! Apparently they don't take "reviews".

In any case we got **very positive reviews back from *PLoS Pathogens*** today, and the revised ms was just resubmitted (<24 hour turnaround). Woohooo! Finger's crossed that the editors turn it around again quickly and we can see this published soon.

Attached is the cover letter, response to reviewers, and the resubmitted version of ms.

Cheers,
Kevin and Paul

We are currently following up some leads for "sponsorship" of our paper with PNAS which would make it an invited piece. If you have any specific suggestions in this regard, please let me know.
>
> As before, the plan is once we submit (hopefully this week) to *PNAS* we will also post as a pre-print on BioRxiv so it can be viewed and used immediately. **If there are any objections to this plan or to submit to *PNAS*, please let me know.**
>
> Also, for those that have secured USG approval already, please let me know if these needs to be updated or if you need any more information.

This has been a fantastic exercise in group writing! Big thank you to everyone.

Cheers,

Kevin

Abstract

The COVID-19 pandemic highlights the substantial public health, economic, and societal consequences of virus spillover from a wildlife reservoir. Widespread human transmission of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) also presents a new set of challenges when considering viral spillover from people to naïve wildlife and other animal populations. The establishment of new wildlife reservoirs for SARS-CoV-2 would further complicate public health control measures and could lead to wildlife health and conservation impacts. Given the likely bat origin of SARS-CoV-2 and related beta-coronaviruses (β-CoVs), free-ranging bats are a key group of concern for spillover from humans back to wildlife. Here we review the diversity and natural host range of β-CoVs in bats and examine the risk of humans inadvertently infecting free-ranging bats with SARS-CoV-2. Our review of the global distribution and host range of β-CoV evolutionary lineages suggests that 40+ species of temperate-zone North American bats could be immunologically naïve and susceptible to infection by SARS-CoV-2. We highlight an urgent need to proactively connect the wellbeing of human and wildlife health during the current pandemic, and to implement new tools to continue wildlife research while avoiding potentially severe health and conservation impacts of SARS-CoV-2 "spilling back" into free-ranging bat populations.

TEXT

Spillover of Pandemic Viruses.

The threat of emerging infectious diseases (EIDs) to wildlife health and biodiversity conservation is recognized [1], but cross-species transmission of novel pathogens, or spillover, is typically

viewed in the specific context of originating *in* a wildlife reservoir and transmitting *to* humans [2]. Research assessing EID risk has typically focused on identifying geographic regions [3, 4] and wildlife species [5-7] whereby spillover of zoonotic diseases into humans is most likely. Among recent pandemic zoonotic viruses, some have no evidence of transmission back to wildlife or domestic animal populations after establishment in people (e.g., human immunodeficiency virus, which causes acquired immunodeficiency syndrome), while others have repeatedly crossed species boundaries (e.g., pandemic H1N1 influenza A virus) [8, 9]. Evidence of 'reverse zoonotic' transmission, sometime referred to as "spillback", from people to wildlife and domestic animals is widespread [9]; however systematic surveys to determine the proportion of EIDs that spill back into novel wildlife hosts are lacking. Infection of bats by viruses of probable human origin has been recorded only twice [10, 11], and further transmission [12], or spread to a wider bat population, has not been recorded.

In December 2019, a novel coronavirus was detected from a cluster of 41 atypical pneumonia cases in Wuhan, China, and has since spread to cause a pandemic with significant global morbidity, mortality, and economic impact [13]. Phylogenetic evidence suggests that this virus, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), and the clade of SARS-related coronaviruses (SARSr-CoVs) that it belongs in, evolved in Old-World bats of the family Rhinolophidae [14-16]. There is no epidemiological evidence of direct or indirect transmission of SARS-CoV-2 from bats to people, but a full genome of its closest known relative, with 96.2% sequence similarity, was reported from an Intermediate Horseshoe Bat (*Rhinolophus affinis*) sampled from Yunnan province, China, in 2013 [17]. The timing of SARS-CoV-2 spillover from bats, and any involvement of intermediate host species, remain undetermined [18, 19]. The United States (US) currently has the highest number of confirmed human cases of COVID-19, the disease caused by SARS-CoV-2. The consequences of this pandemic are many and include

the possibility of SARS-CoV-2 transmission from humans to free-ranging wildlife populations. Given the likely bat origin of SARS-CoV-2, free-ranging bats are a key group of concern for spillover from humans. Humans frequently handle and come into close contact with North American temperate-zone bats during the course of ecological research, wildlife rehabilitation, wildlife/pest control, and disease investigations. Anticipating the need for similar risk assessments across many potentially vulnerable species of wildlife and domesticated mammals globally, here we examine the possibility of humans inadvertently infecting free-ranging North American bats with SARS-CoV-2. We further discuss the possible public health and wildlife conservation consequences of SARS-CoV-2 becoming endemic in bats outside its natural host range.

Threats of SARS-CoV-2 to North American Bats.

The pandemic spread of SARS-CoV-2 may directly or indirectly threaten North American bat populations in at least three different ways. First, SARS-CoV-2 might infect any of the diverse and historically isolated 40+ endemic species of temperate-zone North American bats, with or without causing disease, morbidity, and mortality. Second, SARS-CoV-2 might infect and become established in one or more North American bat species, creating novel reservoirs capable of causing human infections (e.g., bat rabies lyssaviruses in the New World [20]). Third, if SARS-CoV-2 infection persists in North American bats of one or more species, it could potentially evolve, or recombine with endemic viruses [19, 21], to become more pathogenic or infectious to humans or other animals. In addition to new public health challenges, the latter outcomes could quickly shift public perception of bats from mostly beneficial wildlife with associated disease risks that are manageable, to bats posing unacceptable disease risks to human and animal health. Such a shift could increase the likelihood of negative human-bat interactions and conflicts, as well as undermine decades of concerted science, conservation,

and education efforts aimed at conserving these valuable animals [22-24]. The potential threat of SARS-CoV-2 transmission from humans to other animals applies to many species of wildlife and domesticated mammals, but the likely bat origin of SARS-CoV-2, and the current threats to bat populations due to another disease in North America, influenced us to focus this review on bats.

Lessons from an Epizootic -- Susceptibility of North American Bats to an Introduced Pathogen.

SARS-CoV-2 is not the first pathogen with the potential for inadvertent spread from people to North American bats. The COVID-19 pandemic follows the arrival of a fungal pathogen (*Pseudogymnoascus destructans*) that as early as 2006 began infecting hibernating bat populations in North America, spreading within and among species to alter the evolutionary trajectory of the continent's bats [25-28]. Genetic analyses indicate that *P. destructans* was introduced to North America [29], in our opinion likely by movement of humans or materials contaminated with fungal spores. White-nose syndrome (WNS), the disease caused by *P. destructans,* remains the only documented bat epizootic to cause multi-year, widespread mass mortality [30], although short-term bat die-offs have been also linked to Lloviu virus in Europe [31]. WNS has killed millions of North American bats, affected populations of at least 12 species of 3 genera, and has already spread across half of the US and Canada (whitenosesyndrome.org, accessed 11 May 2020). Effective methods to mitigate WNS spread and impacts remain elusive despite substantial research effort, and targeted mitigation actions have had limited success against its impacts [32]. It took years of concerted international scientific effort to identify the cold-growing fungus, determine that it likely originated somewhere in the temperate zones of Europe or Asia, understand its mechanisms of infection and

146 pathogenicity, develop strategies to limit accidental translocation, and track its rapid spread
147 through an immunologically naïve continental assemblage of hibernating bats [33-35].
148
149 The devastating impact of WNS on a diverse group of North American bats likely resulted from
150 evolutionary isolation of the continent's bat fauna from other parts of the world for millions of
151 years, despite other species of *Pseudogymnoascus* being present. Bats in both Europe and
152 Asia can become infected by *P. destructans*, but do not suffer mass mortality from WNS [36,
153 37]. The bat fauna spanning the higher latitudes of North America (in the US and Canada) is
154 composed almost entirely of endemic species belonging to the family Vespertilionidae.
155 Vespertilionid bats occur globally, but likely originated and diversified in North America tens of
156 millions of years ago before dispersing to other continents [38, 39]. No extant species of bat in
157 the Americas also occurs outside of the Americas [40, 41], and no bats migrate across the
158 Pacific or Atlantic oceans [42, 43]. The WNS epizootic demonstrates that a large proportion of
159 these historically isolated bats can be vulnerable to a pathogen introduced from another
160 continent during a single event. Additionally, bats already in a physiologically stressed condition
161 due to WNS or other pressures may be more susceptible to viral infection, experience
162 exacerbated disease outcomes, and/or increased viral shedding [44, 45]. The COVID-19
163 pandemic resembles WNS with respect to potential spread of a pathogen from another
164 continent through interconnected, multi-species assemblages of North American bats that might
165 be immunologically naïve, and highlights deficits in our understanding of temperate-zone bat
166 pathogens in North America.
167
168 **Gaps in Understanding Global Patterns of Bat-CoV Diversity, Evolution, and Host Range.**
169 Bats are among the world's most diverse mammals (approximately 1,400 species [46]), and the
170 global distribution and diversity of CoVs in bats proportionally reflects that of their hosts [47, 48].

Available evidence indicates that bats are natural reservoirs of CoVs, some of which have the potential to cause diseases in humans, domesticated animals, and wildlife [17, 47, 49-59]. Coronaviruses appear to have ancient and ancestral relationships with bats, diversifying globally through a process of within-host evolution and cross-taxonomic host-switching events [47, 59-61]. Bats are the likely mammalian progenitor hosts of all alpha (α-) and beta (β-) CoVs [58, 59, 62, 63] and potentially all coronaviruses [60]. Alpha-CoVs of likely bat origin include the causative agent of swine acute diarrhea syndrome (SADS), which caused mass mortality of over 25,000 piglets on farms in Guangdong province, China [57], and a variant strain of porcine epidemic diarrhea virus (PEDV) that spread rapidly from China in recent decades and caused mass piglet mortality in multiple US states [64]. Human CoVs NL63 and 229E also likely had their evolutionary origins in bats [59, 65]. Two recent human disease epidemics (severe acute respiratory syndrome [SARS], Middle East respiratory syndrome [MERS]) and now the current COVID-19 pandemic are caused by viruses that probably originated from β-CoVs circulating in bat populations in regions where outbreaks occurred [17, 19, 50-54, 58, 66-68].

The emergence of diseases like SADS, PEDV, SARS, MERS, and now COVID-19 strongly indicates a close association between CoVs that become pathogenic in humans and the wildlife reservoirs from which they originate [17, 50-54, 67]. The evolutionary relationships of CoVs within bats are consistent with geographically structured transmission cycles, with occasional transmission among related bat species [47, 58, 69]. These phylogeographic factors are also universal determinants of viral sharing among all mammals [70]. However, bat-virus association patterns can be particularly difficult to discern because bats often roost together in multi-species aggregations that can facilitate viral sharing, with each species capable of harboring multiple CoV lineages [47, 58, 68, 71]. Host shifts from bats to more divergent taxa are more difficult to predict -- firstly, because the potential host breadth for many CoVs is broad [55, 56, 60, 72],

196 and, secondly, because host susceptibility and onward transmission involve complex, multi-
197 stage processes [2, 12]. Bat-CoV associations likely remain substantially under-sampled and
198 understudied in temperate-zone North America [47, 71, 73, 74].
199
200 **Are Viruses like SARS-CoV-2 Already Present in North American Bats?**
201 Our examination of CoV evolutionary lineages and global distribution patterns of the diversity of
202 bat species they infect suggests that temperate-zone North American bats could be
203 immunologically naïve to infection by viruses like SARS-CoV-2. Alpha and β-CoVs have been
204 detected in bats on most continents, sometimes with both types occurring in bats of the same
205 species [58, 68]. However, an exception to this pattern is the lack of published evidence that β-
206 CoVs infect bats of temperate-zone North America, despite several search efforts which used
207 methods suitable to detect both α- and β-CoVs [59, 71, 74, 75]. Multiple novel α-CoVs have
208 been detected and described in vespertilionid bats of the US and Canada, infecting species
209 both living in close contact with humans and in remote wild areas [59, 71, 74-76]. However,
210 SARSr-CoVs and β-CoVs of the viral subgenus *Sarbecovirus* have thus far been detected
211 almost exclusively in species of the Old-World Chiropteran suborder Yinpterochiroptera (Fig.
212 1*A*, Table S1) [47, 58, 69]. The few exceptions to this pattern are the detection of novel Clade 3
213 and Clade 1 *Sarbecovirus* (*sensu* [53]) viruses in the Wrinkle-lipped Free-tailed Bat (*Mops*
214 *plicatus*, family Molossidae) in China [77] and the vespertilionid Leisler's Noctule (*Nyctalus*
215 *leisleri*) cohabiting a Bulgarian cave during autumn with several species of rhinolophids in which
216 other SARSr β-CoVs were concurrently detected, suggesting cross-species infections (Fig. 1 *A*)
217 [78]. Putative detections of a Clade 1 *Sarbecovirus* were also reported from guano samples of
218 the vespertilionid Brown Long-eared Bat (*Plecotus auritus*) and the molossid European Free-
219 tailed Bat (*Tadarida teniotis*) on Sardinia, where the same novel β-CoV was described in the
220 Greater Horseshoe Bat (*R. ferrumequinum*) [79].

Viruses in the β-CoV subgenera *Hibecovirus* and *Nobecovirus* also have been reported mostly from Old-World bat families Rhinolophidae, Hipposideridae, Rhinonycteridae, and Pteropodidae, except for novel viruses of the latter subgenus detected in four species of the vespertilionid genus *Scotophilus* in Asia and Africa (Fig. 1 *B* and *C*; Table S1) [47, 58, 69].

Bat β-CoVs of the subgenus *Merbecovirus* (MERS-related lineages) occur in a greater diversity of bat families and across more global regions than the other subgenera (Fig. 1 *D*) [47, 58, 69]. These widely distributed MERS-like viruses can cause disease in humans (e.g., MERS) and notably appear to be the only bat β-CoVs to diversify among several families of the globally distributed suborder Yangochiroptera (Fig. 1 *D*, Table S1) [47, 58, 69].

Lack of Evidence for β-CoVs in Temperate-zone North American Bats.

The several hundred species of extant bats spanning the Americas all belong to the suborder Yangochiroptera, which likely diverged from the Old-World suborder Yinpterochiroptera more than 50 million years ago (Fig. 2) [80]. The only β-CoVs detected in the Americas to date belong to the subgenus *Merbecovirus*, and appear restricted to two exclusively Neotropical bat families (Phyllostomidae and Mormoopidae) and one that is globally distributed (Molossidae). Distinct CoV lineages in the subgenus *Merbecovirus* were described from three species of *Pteronotus* (family Mormoopidae), four species of *Artibeus*, and Seba's Short-tailed Bat (*Carollia perspicillata*; family Phyllostomidae) from tropical regions of Mexico (Table S1) [47, 81]. Novel β-CoVs of the subgenus *Merbecovirus* were detected in two neotropical bat species of the family Molossidae: Wagner's Bonneted Bat (*Eumops glaucinus*) in southern Brazil and the Broad-eared Free-tailed Bat (*Nyctinomops laticaudatus*) in southern Mexico [81, 82]. *In vitro* infections have shown that primary kidney cells from the Jamaican Fruit-eating Bat *Artibeus*

246 *jamaicensis* can be infected with MERS-CoV, and virus replication and shedding was reported
247 in experimentally-infected bats of this species, but without obvious clinical signs of disease [83].
248 Similar to the evidence for natural invasion of bat rabies viruses among New World bats [84],
249 available evidence suggests β-CoVs may have arrived through South America and have long
250 been evolving in Neotropical bats. Although some bat hosts of *Merbecoviruses* overlap
251 geographically with species of temperate-zone North American bats, none occur outside of the
252 Neotropics. Sampling has been limited, but we are not aware of any published detections of
253 *Merbecoviruses* or any other β-CoVs in temperate-zone North American vespertilionid bats.
254
255 Our inference of true patterns of CoV occurrence and distribution in bat populations is limited by
256 uneven global sampling. Yet, SARSr-CoVs (*Sarbecovirus* spp), a focus of many surveillance
257 efforts, have been almost exclusively documented in Old-World Yinpterochiroptera. SARSr-
258 CoVs were only found in the ultra-diverse and globally distributed bat suborder Yangochiroptera
259 under conditions with plausible transmission from co-roosting *Rhinolophus* sp. bats [53, 85].
260 This absence of evidence for SARS-like β-CoVs in yangochiropteran bats in general, and in
261 temperate-zone vespertilionid bats of North America in particular, likely represents a unique
262 biogeographic pattern driven by underlying factors of host susceptibility or life history. These
263 observations also point to the susceptibility of vespertilionid bats under circumstances of
264 SARSr-CoV environmental exposure, and that they may not be naturally immune to these
265 viruses.
266
267 Bats rank among the most ecologically important mammals and play varied roles in most of
268 Earth's ecosystems; bats pollinate and disperse seeds of numerous plants in tropical regions,
269 and all over the world bats are primary nocturnal predators of flying insects [23, 24]. Across the
270 Holarctic, chiropteran species diversity is greatest among hibernating vespertilionid bats. At

least 25 of the ecologically diverse vespertilionid species of bats in the US and Canada hibernate [86], which might influence their susceptibility to or interactions with viruses, as has been postulated for common vespertilionids infected with α-CoVs and rabies virus [44, 87-89]. Hibernation strategies vary among species of bats (e.g., degree of sociality, thermoregulatory behaviors, habitat selection) [90], but bat body temperatures during hibernation generally remain consistently below 10ºC for periods lasting 7-9 months per year [91], providing a potential mechanism to limit viral replication and spread [92]. Experimental studies to assess the ability of SARS-CoV-2 or other β-CoVs to survive and replicate in bats (cell lines and individuals) at low temperatures [92, 93] would provide additional insight into risk of reverse zoonosis. However, appropriate tools for studying such possibilities are lacking, particularly immortalized cell lines from several hibernating, vespertilionid bats [59]. These tools would also enable interrogation of other physiological features of vespertilionids that may influence susceptibility, such as receptor-binding affinity and the expression of receptors across tissues. Scientists did not discover and isolate the obligately psychrophilic fungus that causes WNS until they collected samples in bat hibernation sites and moved culture dishes for incubation into laboratory refrigerators [25]. Similar innovative explorations outside the typical temperature conditions of laboratory experimentation could help assess risk of SARS-CoV-2 infecting the more than two dozen species of bats in the US and Canada that hibernate to survive harsh temperate-zone winters.

Proactively Connecting the Wellbeing of Human and Bat Populations.

Scientists have long recognized the risk of pathogen spillover from humans to bats [94-96], but bat researchers in North America have not systematically addressed this risk prior to WNS. Outside of reservoir host studies, few bat researchers studied infectious diseases in bats before WNS emerged in 2007 [73], nor studied bat viruses (other than rabies) before bats were

296 retrospectively connected to the SARS epidemic [15, 66, 97]. Fortunately, bat and wildlife
297 disease researchers recently began addressing these knowledge gaps in more detail [7, 97, 98].
298 Possible explanations for why bats might host particularly pathogenic viruses include
299 characteristics of their life history (e.g., long-lived, wide ranging, multi-species aggregations,
300 daily and seasonal heterothermy) [97], unique physiology for repairing their damaged DNA [99],
301 unique ability to suppress some of their innate immunity pathways [100-105], high species
302 diversity [48], and unmatched metabolic range and high body temperatures during flight [106].
303 Bats also cryptically come into close contact with humans, increasingly in urban and peri-urban
304 settings as a result of native habitat loss, often crossing human-wildlife interfaces [107-113].
305
306 Except for *Lyssavirus* infections, bats rarely show substantial signs of sickness from the same
307 pathogens that cause virulent disease in humans. Bats cope with viral infections in ways that we
308 do not yet fully comprehend but learning how they do so may reveal important insights to
309 develop therapeutics and ultimately to protect human health [103-105]. *In vitro* and laboratory
310 studies demonstrate that bats can specifically regulate naïve immunity pathways to effectively
311 cope with viral infection [114]. For example, dendritic cells generated from the bone marrow of
312 the Egyptian Rousette (*Rousettus aegyptiacus*) infected with Marburg virus downregulate
313 immune-stimulatory pathways and maturation of cells targeted by the virus, while upregulating
314 pathogen-sensing pathways [115]. Unique bat immune regulation may occur with MERS-CoV
315 infection, at least under experimental conditions [101]. Egyptian Rousette bats experimentally
316 challenged with SARS-CoV-2 by intranasal inoculation became transiently infected, shed virus,
317 and one co-housed bat became infected, but showed no clinical signs of disease other than
318 rhinitis [116]. Our potential lack of understanding of clinical signs of illness in bats and the
319 cryptic habits of many species also generally inhibit our ability to easily detect spillover of
320 pathogens from human to bat populations. This may add to uncertainty about cross-species

transmission and dispersal of CoVs among human and animal communities. Laboratory findings suggest human viruses that likely originated in bats, such as HCoV-NL63, are capable of infecting bat cells, at least *in vitro* [59]. SARS-CoV-2 and other CoVs have some of the longest genomes among all RNA viruses and despite having specialized RNA proofreading machinery [117, 118], they are still prone to recombination and copy errors in hosts, sometimes resulting in functional adaptations (e.g., altered receptor binding capacity or temperature adaptation of enzymes) [119]. CoVs can even recombine with functional fragments of other virus families, such as when a bat-derived CoV gained a functional gene from a reovirus [21]. Spillover of SARS-CoV-2 from infected humans to North American bats they handle or come in close contact with could lead to the virus becoming either less or more pathogenic to bats or other wildlife, domesticated animals, or humans through genetic mixing in one or more novel hosts. The public-health and conservation consequences of a more virulent virus could be severe, whereas genetic mixing in a bat host that resulted in a less-virulent virus might go unnoticed.

Need for an Interdisciplinary Response.

Effectively managing risks of human disease caused by emerging zoonotic pathogens *and* ensuring the health and conservation of wildlife species, that are potential reservoirs of those disease agents, can be synergistic goals under a One Health framework. Spillover risk (from or to wildlife) is often greatest in disturbed ecosystems where there is an elevated frequency of human-wildlife interactions or disruption of ecological patterns [3, 120-124]. Thus, effective bat conservation and management requires understanding both pathogens that cause disease in bats, as well as human activities and ecological contexts that increase direct and indirect interactions with bats that could present health risks [2]. Furthermore, fear-based reactions to disease risk from wildlife, such as culling infected bat populations or indiscriminate killing, often have negative unintended consequences for the interconnected health of both humans and bats

(e.g., culling of bats in a Uganda mine led to a more than doubling of Marburg virus prevalence in the bats living there) [30, 125-127]. Temperate-zone vespertilionid bats inhabiting human dwellings in the US and Canada represent a particularly relevant human-wildlife interface, where conservation and management actions to proactively address the potential consequences for pathogen spillover are worth careful consideration [73].

Conservation-compatible surveillance of bat viruses has demonstrated the potential for mutually beneficial collaboration between public health scientists and conservation stakeholders [94, 113, 125, 128, 129]. Disease-focused studies that integrate ecological principles into a rigorous study design provide the most informative context to interpret bat-virus associations and patterns of richness globally [130-132]. Assessing the risks of SARS-CoV-2 spillover into North American bats presents a timely opportunity to form multidisciplinary scientific teams that include experts on emerging infectious diseases and ecologists with expertise on North American bats [128]. Scientists researching emerging infectious diseases can benefit from sampling opportunities and methods that bat researchers have developed for observing, counting, and non-invasively sampling bats [73, 133]. Bat researchers can learn about human and animal health monitoring and supporting laboratory methods, including biosafety, secure handling/transport of CoV-positive samples, and training in the proper use of personal protective equipment (PPE) from professionals with expertise in veterinary and medical sciences [113, 131, 134, 135]. A shared goal of all stakeholders is to identify and implement simple, widely available diagnostic tests for detecting SARS-CoV-2 infection that are species-independent, practical for field and laboratory use, highly specific and sensitive, and that do not require strict biosafety containment [136]. All investigators can also work together to develop mutually beneficial goals, such as joint risk communications to the public with effective and balanced messaging about bat populations and higher risk activities for human-bat contact.

Adopting a precautionary approach in the face of global COVID-19 transmission among human populations, national and international wildlife organizations have advised limiting capturing and handling of bats in the field to minimize the risk of humans infecting wild bats with SARS-CoV-2 until further assessment can be made [137, 138]. The emergence of WNS in 2007 prompted a similar surge in interdisciplinary collaboration that enabled the rapid advances already mentioned and introduced changes to guidance for PPE use and disinfection practices for bat researchers and recreational cavers. Similarly, the emergence of SARS-CoV-2 and other viruses will likely alter the *status quo* of bat research, emphasizing the need to carefully weigh risks and benefits of wildlife research in the context of population-altering diseases. For example, PPE including respiratory protection is a standard practice adopted by many bat virus researchers, but by few others studying and regularly handling bats [134, 139]. The urgent research priority of a rapid, quantitative risk assessment and analysis of various mitigation options is currently underway [137, 140]. One key question is whether the proper use of optimal PPE, including bidirectional N95 or equivalent masks, along with effective risk communication and adherence to other basic biosafety practices [134, 141, 142] during field work, can significantly reduce the transmission risk of SARS-CoV-2 from humans to bats. In the interim, until new guidelines are established for handling and for close-proximity work with bats, we have outlined gaps in our understanding of SARS-CoV-2 spillover risks at the interface between humans, domesticated animals, and free-ranging wildlife. Temporarily shifting to 'hands-off' bat research methods also seems prudent, wherever possible, and could facilitate ongoing work with reduced risk.

Examples of 'Hands-off' Research Strategies.

Multiple research strategies that do not involve close contact with free-ranging bats already exist for addressing critical gaps in understanding CoV diversity, distribution, evolution, and potential health effects in temperate-zone bats. For example, a combination of host-cell receptor analyses and *in vitro* and *in vivo* experimental infections across a diversity of bat and other mammalian species have helped inform potential host range expansion for SARS-CoV-2. The receptors that many CoVs use to gain access to host cells, such as angiotensin-converting enzyme 2 (ACE2) and dipeptidyl peptidase-4 (DPP4/CD26), have undergone positive selection in bats, resulting in diverse and recombinant CoV strains [72, 143]. These strains can likely bind to numerous variants of a host receptor protein and facilitate spillover into other animal species [72, 144]. SARS-CoV-2 targets and strongly binds to mammalian ACE2 cell receptors [72, 145, 146]. Beta-CoVs of the subgenus *Merbecovirus* (like those known to occur in the Americas) are not known to target ACE2 cell receptors, instead using as a receptor DPP4/CD26 or possibly other receptors [53, 144]. Current *in silico* predictions that bats will likely have low susceptibility to SARS-CoV-2 based on ACE2 structural analyses conflict with *in vitro* evidence and do not comprehensively account for ACE2 amino acid sequence variation (including intraspecific variation) that occurs within bats [17, 72, 145]. Assessing SARS-CoV-2 host range will require additional virus-host receptor binding assays *in silico* and *in vitro* [17, 53, 72, 144, 145], together with future experimental infection studies for confirmation of Koch's postulates. In addition, *in vitro* studies could evaluate species variability in innate immune responses. These investigations will help quantify the potential for North American bat infection and transmission among free-ranging populations.

Examples of other 'hands-off' methods applicable to both bat disease and conservation research include: virus discovery and characterization focused on existing specimens archived in scientific museums or through partnerships and collaboration with established national bat

disease monitoring or surveillance programs [147, 148]; monitoring echolocation calls to determine the occurrence, distributions, and seasonal or nightly activity patterns of bats [133, 149]; digital imaging methods for counting bats and studying physiology and behaviors in the context of disease [90, 108]; sampling guano from below bat roosts to determine bat species and individual identity, population dynamics, and daily or seasonal patterns of bat occupancy and pathogen shedding [71, 150-152], and mathematical modeling to predict susceptible host species, virus sharing among hosts, spread patterns, or to estimate mortality in affected populations [5, 70, 122, 135]. Promising areas for innovation include making technologies for bat research more accessible to a broader global user base, less expensive, easier to use, and scientifically reproducible through open-source hardware, software, and laboratory methods [153, 154]. In addition to research, standardized field protocols and probabilistic sampling strategies are needed for monitoring bats and their viruses at continental scales (www.nabatmonitoring.org) [155, 156], as are longitudinal studies across multiple sites to better understand the ecological drivers of CoV dynamics and spillover [157]. Developing simple management tools and methods for rapidly assessing risks of virus spillover from humans to wildlife, while maintaining scientific rigor, could also help with future disease response. It might also be useful to prepare a suite of tools, protocols, and risk communication strategies for natural resource managers and public health officials to immediately deploy while risks are being assessed. Such prepared management resources could include public outreach material and guidelines for enhanced use of PPE for those in closest contact with potentially susceptible wildlife.

Conclusion.

Many questions remain about the risk of SARS-CoV-2 to naïve wildlife populations, the influences of human behavior on those risks, and the potential for establishment of new CoV

445 reservoirs. Cross-species virus transmission events are relatively rare, requiring an infectious
446 reservoir host to be in contact with a recipient host when conditions concurrently favor
447 susceptibility and onward transmission [12, 113, 114]. The currently unknown, but possible and
448 potentially high-consequence, risk of SARS-CoV-2 transmission and establishment in North
449 American bats (or other free-ranging mammals) warrants precaution [116, 140]. Strategically
450 managing interactions between people and potentially susceptible or at risk species can
451 decrease the probability of cross-species virus spillover [113]. Humans that frequently handle
452 and come into close contact with North American temperate-zone bats, such as bat
453 researchers, wildlife rehabilitators, wildlife/pest control workers, and disease investigators, can
454 help decrease any chances of spillover by adopting basic PPE and biosafety practices and
455 carefully evaluating how their actions might adversely affect bat populations. We are at a critical
456 nexus of biosecurity and natural resource conservation that will require ingenuity and diligence
457 to continue important research on bats whilst simultaneously evaluating the ecological future of
458 SARS-CoV-2. Our actions during this current pandemic could profoundly influence and protect
459 the health of both humans and wildlife in North America.

Detailed Response to Reviewers -- COMMENTS FROM AUTHORS IN BLUE

Manuscript #PPATHOGENS-D-20-01177

Dear Dr. Olival,

Thank you very much for submitting your manuscript "Title - Possibility for reverse zoonotic transmission of SARS-CoV-2 to free-ranging wildlife: a case study of bats

Short Title - Possibility for SARS-CoV-2 transmission from humans to free-ranging bats" for consideration at PLOS Pathogens. As with all papers reviewed by the journal, your manuscript was reviewed by members of the editorial board and by several independent reviewers. The reviewers appreciated the attention to an important topic. Based on the reviews, we are likely to accept this manuscript for publication, providing that you modify the manuscript according to the review recommendations.

Reviewer #1: This review discusses the possibility of SARS-CoV-2, now circulating worldwide, being introduced into naïve bat populations in North America. This is a prescient warning, as related beta-coronaviruses do not normally circulate in bats in this region of the world, therefore their accidental 'reverse zoonosis' into a new geographically-limited host population would have new implications for both disease in wildlife, and potentially the evolution of further SARS-CoV-2 variants with zoonotic potential. Both of these aspects are discussed thoroughly in the review, which covers strategies to mitigate the risk to bats of SARS-CoV-2 when doing field research on bats, as well as the necessary types of laboratory experiments and analyses required to understand the susceptibility of North American bats to SARS-CoV-2. The text is well written, and both authorative and informative. Furthermore, the figures are clear and visually appealing. The review will be of wide interest to those in the fields of zoonotic and pandemic infectious diseases, as well as bat researchers in general.

I have only one very minor point for the authors to check:

Lines 325-326: when referring to reference 101, is it fair to name SARS-CoV-2, as presumably the work in that manuscript did not include SARS-CoV-2?

Author Response: Thank you for catching this. We agree that SARS-CoV-2 should not be mentioned in this context and removed it from this sentence in the revision. An earlier version of the ms made general reference to lack of a strong immune response in bats during beta-coronavirus challenge experiments and cited the recent infection trial with the fruit bat *Rousettus aegyptiacus* and SARS-CoV-2:

> 116. Schlottau K, Rissmann M, Graaf A, Schön J, Sehl J, Wylezich C, et al. Experimental transmission studies of SARS-CoV-2 in fruit bats, ferrets, pigs and chickens. The Lancet. 2020. doi: https://dx.doi.org/10.2139/ssrn.3578792.

To recapture the prior point and update the revised manuscript with the latest published research, we also added the sentence:

> Unique bat immune regulation may occur with MERS-CoV infection, at least under experimental conditions [101]. **Egyptian Rousette bats experimentally challenged with SARS-CoV-2 by intranasal inoculation became transiently infected, shed virus, and one co-housed bat became infected, but showed no clinical signs of disease other than rhinitis [116]**.

Please note that we also added reference [116] to the Conclusion section and provided a new citation to a USGS risk assessment report now published as reference [140].

Reviewer #2: The review article addresses a relevant and timely topic that has not been reviewed before. It is well structured, well written and discusses available data and possible implications carefully. In only have a few minor points to address:

L.124: Please add a reference for the bat rabies lyssavirus distribution.

"Second, SARS-CoV-2 might infect and become established in one or more North American bat species, creating novel reservoirs capable of causing human infections (e.g., bat rabies lyssaviruses in the New World **[20]**)."

> 20. Banyard, A.C., A. Davis, A.T. Gilbert and W. Markotter. 2020. Bat Rabies. *In* Rabies: scientific basis of the disease and its management (Fooks, A.R. and Jackson, A.C. eds), Academic Press. Pp 231-276.

L.163-170: In my opinion, the text does not require so much detail on the Vespertilionidae family, e.g. the fact that they are "the only bat family to increase in diversity northward out of the tropics and consistently reach high latitudes" seems irrelevant to me regarding susceptibility of this family to a new pathogen. I suggest shortening of this paragraph.

We agree. The point of introducing the bat family Vespertilionidae here in such detail was to set up later findings and discussion about their historical isolation in North America. We hope the more concise revised version achieves this goal. The revision, shown here with text struck and additions in bold, now reads:

> The bat fauna spanning the higher latitudes of North America (in the US and Canada) is composed almost entirely of **endemic** species belonging to the ~~world's largest bat~~ family ~~–~~Vespertilionidae~~, with at least 500 described species [38]~~. Vespertilionid bats occur globally, but likely originated and diversified in North America tens of millions of years ago before dispersing to other continents~~ this second-largest family of mammals is the only bat family to increase in diversity northward out of the tropics and consistently reach high latitudes (50ºN)~~[39, 40]. No extant species of bat in the Americas also occurs outside of the Americas [41, 42], and no bats migrate across the Pacific or Atlantic

oceans [43, 44]. The WNS epizootic demonstrates that a large proportion of these historically isolated bats can be vulnerable to a pathogen introduced from another continent during a single event.

L.174-176: The sentence "The COVID-19 pandemic resembles WNS with respect to potential for pathogen spread through interconnected, multispecies populations" should be explained: Do the authors refer to WNS spread in bat populations or is there also evidence for spread in other animals? If it refers to bat populations is there evidence that SARS-CoV-2 has the potential to spread in multispecies bat populations? To me it was unclear what sort of populations the authors refer to.

We thank the reviewer for pointing out this ambiguity. Part of the problem was that we mistakenly referred to "…multi-species populations…" yet elsewhere always referred to populations in the single-species context. We also did not include any continent-specific wording to make our focus on potentially naïve bat populations of North America more apparent. Our intent was to raise the possibility that SARS-CoV-2 might have the potential to spread through multiple species (and genera) of co-occurring North American bats, as we have seen with the introduced pathogen that causes white-nose syndrome. Therefore, we revised the sentence to read:

> The COVID-19 pandemic resembles WNS with respect to potential ~~for~~ **spread of a** pathogen ~~spread~~ **from another continent** through interconnected, multi-species **assemblages of North American bats** that might be immunologically naïve, and highlights deficits in our understanding of temperate-zone bat pathogens in North America.

Board of Editors
PLoS Pathogens

15 June 2020

Dear Editors,

This letter accompanies our revised manuscript (#PPATHOGENS-D-20-01177) “Possibility for reverse zoonotic transmission of SARS-CoV-2 to free-ranging wildlife: a case study of bats”.

We sincerely thank the editors and reviewers for their overall positive comments on our manuscript, and for considering it for publication in *PLoS Pathogens*. Guided by the very helpful, but relatively minor, reviewer comments we improved the article for this resubmission (**see attached response to reviewers for details**). A version of the manuscript showing all changes we made since submission, including improvements to the references cited section, is included with the revision package.

We hope that our revisions address the concerns raised and that our findings are now suitable for publication in *PLoS Pathogens*.

Thank you again for considering our manuscript.

Sincerely,

Kevin Olival and Paul Cryan

OK folks, you know this is coming, but if PLoS don't like it, EID don't like it, and 2 or three others,*EcoHealth* will be delighted if you submit it there. We will pledge to review it and get it back to you within 3 weeks, and if reviewer's comments are addressed, we will include a color image of your choosing. We'll push Springer to make it available online for free as well. All this assuming it gets through review process. Also, as Editor-in-Chief, I'll be recused automatically from the review process, which is also Double-Blind.

Cheers,

Peter

Hi Folks,

Quick update on our paper — unfortunately got news yesterday that *PNAS* was not interested in this as a Perspectives piece, and rejected our proposal. We are currently pursuing options with editors at *PLOS Pathogens* to see if they want it as a review. Will keep you all posted.

Latest version attached that has cleared CDC and USGS review. We will still aim to get this on BioRxiv, but wanted to wait until we had it cleared first and ideally in review at a journal.

Cheers,
Kevin

Thanks, Rebekah.
I'm glad you thought it was worthwhile. I thought it was really productive, too, and very glad to have you there.
I think Marty, Katie and Megan deserve most of the credit for how well the meeting worked out and the assembly of people, but I'm also giving special props to Tigga for her bat artistry skills (and scientific insight, of course... but mostly drawing :)).

Talk to you soon.

Cheers,
Jon

I know that took an amazing amount of coordination to get so many more people there, and I thought it was a very productive time! It was nice to have formal talks from some folks, and the white paper exercise was a great way to get people working together. I appreciate all the time and energy you each put into BOHRN -- it is a unique group with an important purpose and I am excited about the trajectory we are on so far! I'll look forward to touching base again soon about planning the Uganda meeting in the spring.

Dear BOHRN TRN Steering Committee Members,

We hope you have been able to remain safe during these times and that this email finds you well. As you may already know, the World One Health Congress has been rescheduled to take place on October 30 - November 3 in response to worldwide travel restrictions and to coincide with International One Health Day on November 3rd. We wanted to inform you that the BTRP TRN side meetings have been rescheduled in tandem with the Congress, now aiming to take place on November 3 - 4. This is a change we are trying to implement, however, we understand the current scope of world events and anticipate further changes as we go forward. Our utmost priority is everyone's safety and we will continue to monitor the situation to act accordingly. We will be sure to keep you informed of all updates.

Please let us know if you have any questions and stay safe.

Kind Regards,

Subject: World One Health Congress and BTRP TRN Side Meeting - BOHRN

Dear BOHRN TRN Steering Committee Members,

On behalf of Dr. Martha Stokes, please accept this Save the Date to attend the World One Health Congress in Edinburgh, Scotland 15-17 June 2020 and participate in side meetings on BTRP's Threat Reduction Networks and planning for BOHRN.

Tentatively, we plan to hold two sessions at the end of the week: Thursday, 18 June - an afternoon TRN session that will include a wide group of BTRP-funded participants from its other research networks to discuss network metrics for sustainability; Friday, 19 June - a side meeting for BOHRN to map out its schedule and strategy, aligning with funding opportunities from BTRP and other entities. Attached is a tentative schedule for the week, for your reference. Due to travel and budgetary constraints we are unable to invite the entire steering committee, but intend to have productive discussions and meet objectives with the smaller group on this Save the Date email.

Please let us know if you will be able to attend the WOHC and side meetings on 18-19 June. Official invitation with travel instructions, details on arrangements, and more formal agenda will be forthcoming. Please note that there is a potential for the WOHC and BTRP side meetings to be postponed, given the current travel uncertainties related to COVID-19. We will be monitoring the status of the conference, and will keep you apprised of any cancellations should they occur. As always, let us know if you have any questions!

We hope to see you in Edinburgh!!

V/r,
Caitlin Devaney

Greetings everyone! Thank you for the update - I will stay tuned to see how the situation unfolds. I am available on those dates should that work out. We could try a Zoom meeting sometime in the interim, if that would be helpful to get everyone "together"? I know many BOHRN members have been collaborating and contributing to the pandemic response in a variety of ways, which I think represents some successful grassroots mobilization of the network. Might be encouraging to have something of a group call to hear about what folks have been up to and if there's anything we can band together more formally to accomplish despite being scattered. Just an idea to throw out there!
Kind regards,
Rebekah

Dear BOHRN TRN Steering Committee Members,

We hope you have been able to remain safe during these times and that this email finds you well. As you may already know, the World One Health Congress has been rescheduled to take place on October 30 - November 3 in response to worldwide travel restrictions and to coincide with International One Health Day on November 3rd. We wanted to inform you that the BTRP TRN side meetings have been rescheduled in tandem with the Congress, now aiming to take place on November 3 - 4. This is a change we are trying to implement, however, we understand the current scope of world events and anticipate further changes as we go forward. Our utmost priority is everyone's safety and we will continue to monitor the situation to act accordingly. We will be sure to keep you informed of all updates.

Please let us know if you have any questions and stay safe.

Kind Regards,

Subject: Reference for Anna Fagre for EID-Search Research Scientist & Project Manager at EcoHealth Alliance
Attachment(s): "2020 Research Scientist and Project Manager Job Ad.pdf"

Dear Dr. Kading,

We just interviewed Anna Fagre for a position here at EcoHealth Alliance as a Research Scientist and Project Manager. Our hiring committee thought she was terrific with the right background and attitude for our team. Anna listed you as a reference. If you would be willing to send some comments about Anna, that would be terrific!

I have attached our position advertisement, so you may know more about the position - though based on her skillset, the specifics would evolve a bit. This position would focus primarily on our emerging infectious disease projects based in Southeast Asia including our recently awarded, NIAID funded EID-SEARCH program:

- https://www.ecohealthalliance.org/program/south-east-asia-research-collaboration-hub

I look forward to your reply and should a phone call be more convenient, we could do that as well.

On behalf of our whole committee, I sincerely appreciate your time.

-Aleksei

JOB ADVERTISMENT

POSITION TITLE: Research Scientist and Project Manager

POSITION SUMMARY

Reporting directly to the President, the Research Scientist will assist senior research scientists on our NIH-funded and projects to examine the dynamics of pathogen transmission within and among wildlife populations, livestock, and humans; as well as the risk of spillover, patterns of infection, phylogenetic relationships of emerging zoonotic diseases. The candidate should be self-motivated and proactive. The Research scientist will need to have a collaborative approach to research, a positive attitude towards solving complex problems, and creativity. This position is a critical part of our science base and the will actively and collaboratively engage in expanding the boundaries of our research as well as help create our 'think-tank' on emerging infectious diseases. Above all, a passion for understanding the process of zoonotic disease emergence is key.

RESPONSIBILITIES

- Collaborate and/or lead in the design and implementation of a multi-country field study of zoonotic disease emergence from bats, rodents, and primates as well as the role of human behavior in disease emergence and analyze the resulting data. Extensive foreign travel, particularly in southeast Asia will be expected.
- Work on modeling and other projects that broadly integrate evolutionary, ecological, and biodiversity data into emerging disease and zoonotic disease models.
- Liaise with EcoHealth Alliance and other scientists to generate hypotheses and to assist with development of models and plan avenues of scientific investigation
- Engage with EcoHealth Alliance scientists and consortium partners on our other projects as well as on federally funded programs on AI, Ebola, Nipah, RVFV, and other emerging diseases.
- Work closely with the President, science staff, and collaborators to design and execute analytical projects to understand the process of zoonotic disease emergence including examination of the roles of host-specific and evolutionary drivers of disease emergence.
- Represent EcoHealth Alliance and work with stakeholders and collaborators at local, national, and international levels.
- Manage Staff, liaise with international partners, and report proactively to funders
- Assist with grant and manuscript writing
- Be responsible for grant management and program coordination
- Use a strong fact basis and collaborative approach to formulate alternative and creative solutions to problems and sensitive issues.

QUALIFICATIONS

- Minimum of Ph.D. in: Biology, Ecology, Evolutionary Biology, Public Health, or related field in the life sciences
- Strong quantitative analytical skills
- Experience with statistical analyses, particularly using R
- Experience with phylogenetic and evolutionary analyses a plus.
- Previous experience in public health or infectious diseases
- Previous experience writing grants and with international grants and program administration of large projects with key components including field and laboratory work and analyses
- 1-to-3 years' experience working on projects funded by US Federal agencies as well as prior non-profit, academic, or equivalent positions
- Demonstrated writing and research skills including Publications in peer-reviewed scientific journals
- Ability to conduct literature reviews, data collation and cleaning, and exploratory data analyses
- Strong writing and verbal communication skills with a keen eye for detail
- Proven ability to work independently
- Self-driven, highly motivated, organized, and willing to perform research and administrative duties
- Strong interpersonal skills; a willingness to place team before self and a strong sense of diplomacy
- Previous experience in Southeast Asia is a plus
- Cultural sensitivity
- Willingness to work some mornings, evenings, weekends as necessary
- Fluency in written and spoken English required

At EcoHealth Alliance, our vision is a workplace with a diverse and talented staff where people want to come, to stay, do their best work, and grow. We recruit, employ, train, compensate and promote our staff without regard to race, ethnicity, color, religion, gender, gender identity or expression, sexual orientation, national origin, disability, age, veteran status, or socioeconomic status. This position is based at EcoHealth Alliance in New York City and will entail extensive domestic and international travel. EcoHealth Alliance offers a competitive salary and a comprehensive benefit package including health, dental, and vision coverage, and a 403(b) pension plan. EcoHealth Alliance is proud and deeply committed to being an equal opportunity employer. For further information about EcoHealth Alliance, please visit our website: www.ecohealthalliance.org.

HOW TO APPLY

Send an email with a *single* attachment in PDF format containing (a) a cover letter, (b) CV, and (c) three references to jobs@ecohealthalliance.org with "**2020 RESEARCH SCIENTIST AND PROJECT MANAGER JOB APPLICATION**" in the subject line. If you would like to be considered for more than one job position, please indicate that in your cover letter and list your order of preference. Emails without the subject line or with multiple attachments will not be reviewed. No formal text is required within the body of your email, since emails will not be evaluated. All inquiries will receive an automatic response confirming receipt. *Only* appropriately qualified candidates will be contacted. Closing date for this position: 15th July 2020.

Thank you for your interest in EcoHealth Alliance!

Subject: Bat One Health Research Network

Dear all,

On behalf of Dr. Marty Stokes, please find the final report for the BOHRN Workshop in Vienna.

As discussed in Vienna, there are several action items for the BOHRN network. In order to move forward on several of these items, we ask that you take a few moments to answer the following questionnaire. This survey will help us to identify BOHRN's efforts and progress towards its overarching goals and evaluate the networks threat reduction efforts. Please follow the link and complete the survey no later than 28 February: https://www.surveymonkey.com/r/6FQPQR3

Additionally, please use the following Drop Box link for access to the BOHRN Workshop participant list with pictures and the quad charts submitted by all participants. You may also access the video of the BOHRN Workshop here.

We had hoped to make a more formal announcement regarding solicitation for BOHRN special projects around this time; however, BTRP is internally still reviewing necessary criteria for award and will not be ready to make a more formal announcement until the April / May timeframe. The announcement will be released via the www.bohrn.net website.

Please let us know if you have any questions or concerns.

Kind Regards,

Megan

Subject: Reminder: BOHRN November IMED Meeting Invitation

All,

As a reminder, please respond NLT **14 September** if you are able to attend the BOHRN/IMED Meeting in Vienna on 8-12 November 2018. The BOHRN meeting will be held 8-9 November.

We are looking for nominations to grow the BOHRN network, please send any nominations of subject matter experts or other participants who would be beneficial to this discussion **no later than Today, 10 September 2018**.

IMED will take place 9 – 12 November at the Hilton Vienna. The 2018 IMED will focus on innovation and changes in political and societal responses to outbreaks. The theme of IMED aligns with our overall BOHRN objectives and we encourage all BOHRN members to stay and participant in the conference.

We need you to confirm your attendance to BOHRN and IMED NLT 14 September.

Subject: BOHRN November IMED Meeting Invitation

All,

On behalf of Dr. Marty Stokes you are receiving this email, as part of a save the date to attend our BOHRN Steering Committee meeting and International Meeting on Emerging Diseases and Surveillance (IMED) 8 – 12 November 2018 in Vienna, Austria.

Our meeting will take place on 8 – 9 November (hotel/meeting location TBD). The BOHRN steering committee meeting will aim to meet the objectives the group identified in Saskatoon. The following objectives were suggested based on your survey responses:

1. Prioritizes funding needs based on working groups' characterization of gaps and needs, to help organize and develop funding initiatives; and
2. Analyze progress of action plans and their yields establishing collaborate and sustainable projects

To facilitate these objectives, we will be asking each working group to present their progress. The progress updates for each working group are imperative to the outcomes for this meeting.

As discussed during the June BOHRN meeting, an objective of this meeting is to develop our outreach and populate working groups. Please send any nominations of subject matter experts or other participants who would be beneficial to this discussion **no later than 10 September 2018**.

IMED will take place 9 – 12 November at the Hilton Vienna. The 2018 IMED will focus on innovation and changes in political and societal responses to outbreaks. The theme of IMED aligns with our overall BOHRN objectives and we encourage all BOHRN members to stay and participant in the conference. **Therefore, we need you to confirm your attendance to BOHRN and IMED NLT 14 September.**

Attachment(s): "SARSCoV2 Round2 Draft2.pdf"

Hi Expert team,
Thank you so very much for contributing to this assessment, on short notice, and using a process which may have been unfamiliar. Mike and I appreciate your contributions. We also learned a lot from the discussion that has helped us better understand the elements of transmission and infection that will drive the ultimate outcome.

Here I attach the revised distributions for each of the questions, following the discussions we had and your updated estimates. There was considerable revision in your estimates, which came in part from the median estimates but also a revision of the boundary limits and confidence. There remains significant uncertainty, which is expected given the emerging nature of this pathogen. These estimates were useful in estimating the risk of transmission to North American bat populations. We would have been unable to accomplish this without your expert judgement.

We are presenting these results this coming Friday, and cordially invite you to attend. Below please find the instructions to login to the presentation, hosted by Jonathan Mawdsley of the Association of Fish and Wildlife Agencies.

Kindest regards,
Evan and Mike

You are cordially invited to a Zoom presentation on the topic:

Acknowledgments

A guidance committee, composed of representatives from several State and Federal wildlife agencies, was instrumental in helping us frame the decision context for this risk assessment. We are grateful to Jenny Dickson of the Connecticut Department of Energy and Environmental Protection, Owen Boyle of the Wisconsin Department of Natural Resources, Colin Gillin of the Oregon Department of Fish and Wildlife, Carl Herzog of the New York State Department of Environmental Conservation, Richard Reynolds of the Virginia Department of Game and Inland Fisheries, Michelle Verant of the National Park Service, and Patrice Klein of the Forest Service.

The members of the expert panel were instrumental in helping us estimate the underlying parameters in this risk assessment. For their expertise, thoughtfulness, and patience, we thank Raina Plowright from Montana State University, DeeAnn Reeder from Bucknell University, Daniel Streicker from the University of Glasgow (United Kingdom), Jonathan Epstein from EcoHealth Alliance, Christine Kreuder Johnson from the University of California at Davis, Winifred Frick from Bat Conservation International, Jonathan Towner and Brian Amman from the U.S. Centers for Disease Control and Prevention, Alison Peel from Griffith University (Australia), Rebekah Kading from Colorado State University, Amy Gilbert from the U.S. Department of Agriculture-APHIS, Kevin Castle from Wildlife Veterinary Consulting LLC, and Kate Jones from University College London (UK).

Matthew Ferrari from the Pennsylvania State University and Jennifer Schimmel from Baystate Health Division of Infectious Diseases provided insights into the human epidemiology of SARS-CoV-2. Justin Stevenson of RD Wildlife Management and Consulting provided additional context for wildlife control activities. We are grateful to LeAnn White, Katherine Richgels, and Karen Jenni of the U.S. Geological Survey, who carefully reviewed this report and offered suggestions that have improved it substantially.

The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

Assessing the Risks Posed by SARS-CoV-2 in and via North American Bats—Decision Framing and Rapid Risk Assessment

By Michael C. Runge[1], Evan H. Campbell Grant[1], Jeremy T. H. Coleman[2], Jonathan D. Reichard[2], Samantha E. J. Gibbs[2], Paul M. Cryan[1], Kevin J. Olival[3], Daniel P. Walsh[1], David S. Blehert[1], M. Camille Hopkins[1], and Jonathan M. Sleeman[1]

Abstract

The novel β-coronavirus, SARS-CoV-2, may pose a threat to North American bat populations if bats are exposed to the virus through interaction with humans, if the virus can subsequently infect bats and be transmitted among them, and if the virus causes morbidity or mortality in bats. Further, if SARS-CoV-2 became established in bat populations, it could possibly serve as a source for new infection in humans, domesticated animals, or other wild animals. Wildlife management agencies in the United States are concerned about these potential risks and have begun to issue guidance regarding work that brings humans into contact with bats, but decision making is difficult because of the high degree of uncertainty about many of the relevant processes that could lead to virus transmission and establishment. The risk assessment described in this report was undertaken to provide management agencies with an understanding of the likelihood that the various steps in the causal pathways would lead to SARS-CoV-2 infection of North American bats from people. This assessment focused on the active season for bats in the temperate zone of North America (April 15 through November 15), and used *Myotis lucifugus* (little brown bats) as a surrogate species. At the time of this work (April 2020), no empirical data about the effects of SARS-CoV-2 on North American bats were available, so a formal process of expert judgment was used to elicit estimates of the underlying parameters. Twelve experts in bat ecology, epidemiology, virology, and wildlife disease from the United States, United Kingdom, and Australia participated in the elicitation. A Monte Carlo simulation model was used to integrate the parameter estimates elicited from the experts and to predict the likelihood of exposure and infection in bats through a series of transmission pathways, with particular attention to capturing uncertainty in the predictions.

Given the current state of knowledge as expressed by the expert panel, the results of this assessment indicate that there is a non-negligible risk of transmission of SARS-CoV-2 from humans to bats. For example, if a research scientist were shedding SARS-CoV-2 virus while handling bats under the field protocols used in North America prior to the COVID-19 pandemic, the risk model indicates that 50 percent (uncertainty, 15–84 percent) of those bats could be exposed to virus, and 17 percent (uncertainty, 3–51 percent) could become infected. Use of personal protective equipment, especially a respirator, is expected to reduce the exposure risk. The expert panel estimated that exposure risk from research scientists could be reduced 94–96 percent (uncertainty, 86–99 percent) through proper use of appropriate N95 respirators (a type of mechanical filter worn over the nose and mouth), dedicated clothing (such as Tyvek coveralls), and gloves. Should any North American bats become infected with SARS-CoV-2, the expert panel estimated that there is an approximately 33-percent chance the virus could spread within a bat population.

This study, conducted by the U.S. Geological Survey in cooperation with the U.S. Fish and Wildlife Service, identified several critical uncertainties that could affect the estimate of risks associated with SARS-CoV-2 entering bat populations—notably, the underlying probability that a human would be shedding virus while working with bats, the likelihood of the virus replicating in bat tissue, and the likelihood of transmission of the virus within bat populations. Ongoing empirical work during May–October 2020 may shed light on these issues. Follow-up work is needed to better understand the probability of transmission of SARS-CoV-2 to bats from the general public; the manner in which the probabilities of exposure, infection, and transmission would differ during hibernation compared to the breeding season; and the likelihood of important effects, like morbidity and mortality in bats, the possibility of zoonosis from a North American bat reservoir, and effects of and on other wildlife.

Introduction

The novel β-coronavirus, SARS-CoV-2, that has caused a pandemic disease (COVID-19) in humans arose from a mammalian host, possibly an Old World bat in the family Rhinolophidae. The closest known virus discovered in wildlife was found in a *Rhinolophus affinis* (horseshoe bat) from Yunnan province in China (Zhou and others, 2020b), although the similarity is not an exact match. No SARS-related β-coronaviruses have yet been identified in New World bats, but a different type of β-coronavirus has been identified in New World species of bats from Mexico (Anthony and others, 2013; Anthony and others, 2017; Góes and others, 2016). This raises an important question about whether North and South American bats could be vulnerable to infection with SARS-CoV-2 via contact with humans, which in turn raises questions about whether there could be reciprocal spread to humans via a bat reservoir. This inquiry was designed to be a rapid assessment of the risk of transmission of SARS-CoV-2 from humans to North American bats, the management contexts in which this risk might be relevant, and possible mitigation actions that may be implemented by those who come into contact with bats or their habitats. The structure of this study could also serve as a model to rapidly assess the risk to bats in other geographic regions (for example, Europe or Latin America) or the risk to other wildlife taxa of concern (for example, felids and mustelids which may be susceptible to SARS-CoV-2; Shi and others, 2020).

The purpose of this report is to describe the risk assessment conducted by the U.S. Geological Survey, in cooperation with the U.S. Fish and Wildlife Service, to evaluate the potential for transmission of SARS-CoV-2 from humans to bats. This assessment focuses on potential activities undertaken by research scientists, wildlife rehabilitators, and wildlife control operators in North America during the summer field season (April 15 to November 15, 2020), with and without new protocols for such work.

Decision Framework

In late March 2020, State, Federal, and tribal wildlife management agencies in the United States began expressing concern about the possible transmission of SARS-CoV-2 from humans to bats and requested that the U.S. Geological Survey (USGS) lead a risk assessment that could inform their decision making. Prior to designing the risk assessment, the authors worked with a guidance committee composed of representatives from State and Federal wildlife management agencies (see Acknowledgments) to frame the decision context in which risk assessment would be used. We recognized that the motivation, statutory requirements, and authority to address the problem may stem from human health and wildlife conservation interests and needs, and that decisions involve a mixture of conservation and human health objectives, where tradeoffs are likely to occur. The construction of the decision framework was instrumental in informing the focus and structure of the risk assessment. The decision framework constructed in consultation with the representatives from decision-making agencies is described below.

Relevant Decision Makers and their Authorities

In the United States, there are many decision makers with authority to make decisions that affect bats and the interactions of bats and people. For most terrestrial mammal species that are not listed under the U.S. Endangered Species Act (ESA; 16 U.S.C. §1531 et seq.) and are not on Federal land, the State wildlife agencies have management jurisdiction. The status of bats under current State laws and regulations differs from State to State (O'Shea and others, 2018), but existing statutory and regulatory authorities generally involve several types of activity. First, States have authority to direct the activities of their own staff, such as conducting bat surveys or habitat and population management. Second, States permit the work of wildlife rehabilitators and can prescribe conditions of that work. Third, States permit nuisance wildlife control operators who perform such activities as removing bats from human dwellings. Fourth, States provide permits for a variety of research activities by scientists and environmental consultants. Fifth, States sometimes collaborate with educational institutions that may keep captive bats for purposes of exhibition. Sixth, States often require permits or registration for private citizens or groups who wish to hold bats. Seventh, State wildlife agencies, in conjunction with many partner agencies, often undertake public communication about the benefits of wildlife and healthy ways for humans to interact with wildlife.

Several U.S. Department of the Interior (DOI) agencies have management responsibilities for bats. The U.S. Fish and Wildlife Service (FWS) has authority under the ESA for any listed bat species; this authority includes permitting the activities of other Federal agencies that may affect listed species. The FWS Office of Law Enforcement is responsible for managing the importation of wildlife into the country. (The Centers for Disease Control and Prevention (CDC) also require permits for importation of bats). The FWS Wildlife and Sport Fish Restoration Program is a major funding source for State agencies' bat management efforts. The FWS supports the National White-Nose Syndrome Program, which provides funding for research, conservation, and monitoring of bats, and issues guidance to partners on matters related to white-nose syndrome (WNS). The FWS, through the National Wildlife Refuge System, manages land, wildlife, staff, and public access at Refuges, some of which provide habitat for bats. Refuge staff conduct research and monitoring activities. Refuges also issue special use permits for outside scientists to conduct research. Similarly, the National Park Service (NPS) has authority over the activities that occur within NPS

units. These activities include research and management, which involve contact with bats by park staff or cooperators; cave tours and bat viewing opportunities for the public; and permits for recreational caving by individuals or groups. The FWS Refuge System and NPS have extensive communication efforts aimed at educating the public about wildlife, including bats.

Within the U.S. Department of Agriculture, the U.S. Forest Service (USFS) has research and management responsibilities for bats on its Federal lands, often in coordination with other Federal and State partners. Similar to DOI agencies, the USFS manages land, sustains habitat for native fish and wildlife, and provides public access for recreational activities, including use of caves and mines. USFS scientists conduct research and monitoring activities. The USFS issues permits for outside scientists to conduct research on its lands. The National Forest System engages in public outreach and education about wildlife, especially bats.

Many agencies and institutions, including the USGS, FWS, NPS, USFS, universities, and non-governmental organizations, conduct scientific studies on bats. Under the Animal Welfare Act (7 U.S.C. §2131 et seq.) and other Federal and State laws and policies, researchers and agencies are required to consider the welfare of the animals being studied or used for educational or teaching purposes in captivity or the wild. Institutional Animal Care and Use Committees (IACUC) are responsible for review and approval of protocols involving animals used in research or teaching. IACUC review ensures that the welfare of animals is taken into consideration and that all approved activities include appropriate use of animals. Additionally, these entities often conduct internal reviews of scientific research study plans. IACUC and other research plan review mechanisms represent an additional tool with which agencies can manage the activities of their staff that involve interactions with animals.

Public health agencies at Federal, State, and county levels take action to benefit human health, and while they do not directly manage bats, they do play a role in the interactions humans have with bats. Because of the risk of rabies virus transmission, many interactions that members of the general public have with bats are reported to county health agencies, which help to manage the health risk of such exposure. In turn, county health agencies often report rabies statistics to State and Federal public health agencies (for example, CDC), enabling broader understanding of seasonal and geographic patterns and trends in the types of bats and other wildlife coming into contact with the public at a national scale (Pieracci and others, 2020).

Finally, zoos and wildlife parks frequently have captive populations of bats, including species native to North America as well as species from other parts of the world, with which North American bats may not naturally come into contact. Zoos and wildlife parks can control the proximity of humans to captive bats and the way the bats are handled by staff.

Management Objectives

Each agency with jurisdiction that affects the interactions of bats and humans has its own purposes, as derived from its enabling legislation, mission, or stakeholder input. We worked with representatives from State and Federal wildlife management agencies (see Acknowledgments) to develop a set of long-term outcomes (“fundamental objectives”) sought by these agencies through decisions related to bats and SARS-CoV-2. We recognize that some of these objectives may conflict with each other; indeed, that is what makes decisions difficult. By clearly articulating the set of objectives that are important to decision makers, the scientific assessments that are needed to inform difficult deliberations about appropriate and necessary mitigation actions can be better identified. Through discussions with these representatives, 10 objectives were identified. (The order of presentation of these objectives is not meant to imply anything about their relative importance.)

1. Minimize the morbidity and mortality of wild North American bats resulting from infection with SARS-CoV-2 or from management actions meant to mitigate transmission. If SARS-CoV-2 is introduced and transmitted to a naïve population of bats, it is possible the novel infection could lead to disease or death. In addition, some management actions meant to reduce disease transmission to bats could directly or indirectly cause mortality. Because many of these bat populations are already threatened by WNS and other stressors, any additional sources of mortality could affect long-term conservation.

2. Minimize the risk of SARS-CoV-2 becoming endemic in any North American bat population through sustained bat-to-bat transmission. We want to avoid anthropogenic establishment of a new endemic disease in bat populations for several reasons. Fundamentally, any anthropogenic change to the ecosystem outside the course of natural events is to be avoided. We are also concerned about this objective as a means to other objectives because a reservoir of SARS-CoV-2 in bats could lead to a reduction in the long-term conservation of bats (Objective 1), a risk to public health (Objective 3), or a risk to the health of other wildlife taxa or domesticated animals (Objective 5).

3. Minimize the risk of new SARS-CoV-2 cases in humans via transmission from North American bats. The long-term aim of public health agencies and other organizations will be to minimize the incidence and transmission of SARS-CoV-2 in humans. However, if a reservoir of SARS-CoV-2 becomes established in North American bats, it could represent a source for new exposure and infection; worse, if such a reservoir provides an opportu-

nity for evolution or recombination of the virus, the new viral strains could evade existing immune responses or reduce the efficacy of vaccines under development.

4. Minimize the indirect effect on human health from actions designed to mitigate SARS-CoV-2 transmission to bat populations. Particularly at this moment, when the equipment needed to manage the COVID-19 pandemic is in short supply, any use of such equipment (such as personal protective equipment; PPE) for bat-related activities may undermine public health efforts. The supply of PPE for human needs is expected to increase in the near future as manufacturing ramps up, decreasing the gap between demand and supply. Therefore, this may not be a limitation once the human health demand is satisfied.

5. Minimize the risk of SARS-CoV-2 infection in other North American wildlife or domesticated animal populations through a reservoir in North American bats. Other species of mammals and other taxa are known to be susceptible to β-coronaviruses, specifically SARS-related viruses. If SARS-CoV-2 becomes established in bat populations, it could possibly spill over into other susceptible wild and domesticated animals.

6. Maintain or maximize the ability of wildlife control operators and wildlife rehabilitators to carry out their functions for the benefit of humans and wildlife. The activities undertaken by wildlife control operators are necessary tools for managing conflict between humans and wildlife; these activities (like humane removal of bats from human dwellings and prevention of ingress) are important for human health (for example, minimizing rabies exposure) as well as for bat conservation. Likewise, the activities undertaken by wildlife rehabilitators may have a positive effect on wildlife, as well as a positive effect on public attitudes toward wildlife.

7. Maintain or maximize recreational activities, such as cave tours, recreational caving, and other activities that occur in bat habitat. Humans derive benefit from outdoor recreational activities; indeed, refuges, parks, and national forests have an important purpose in providing such opportunities.

8. Maximize the opportunities for scientific research on bats and within bat habitat. Research on bats and their habitats contributes to many facets of primary knowledge about the natural world. Conservation measures for other threats to bats, including WNS, benefit from on-going research. Additionally, the status of listed and candidate bat species requires a periodic assessment of population sizes. The fields of geology, hydrology, entomology, and numerous others benefit from on-going research that may overlap with bats and their habitats.

9. Maximize public appreciation for bats and their conservation. Past zoonotic diseases (such as the 2003–10 highly pathogenic avian influenza outbreak and the 2003 SARS outbreak) have created negative public responses to wildlife (wild birds and wild bats, respectively). The risk of SARS-CoV-2 in bats and the response to it could undermine recent gains in public appreciation for bats and bat conservation.

10. Maximize the ability to manage and conserve bat populations. Many of the agencies mentioned above have active programs to conserve bat populations. These programs sometimes require staff to handle or be in proximity to bats. Objectives 6 and 8 also contribute to the long-term conservation of North American bats.

Potential Mitigation Measures

The central causal chain that was motivating concern from State, Federal, and tribal wildlife agencies has three steps: the possible transmission of SARS-CoV-2 from humans to bats; sustained bat-to-bat transmission of SARS-CoV-2; and subsequent effects, for instance, of transmission from bats back to humans or to other wildlife. The representatives from State and Federal wildlife agencies that guided this work expressed an urgent need to identify actions they could take to interrupt this potential chain of events. We worked with the representatives to identify the types of actions within their jurisdiction that could be employed to minimize the risks associated with SARS-CoV-2 and achieve the objectives described above. Each of the decision-making bodies has a different set of management actions under its jurisdiction, and we did not try to match particular actions with specific agencies. Instead, we worked with them to describe the types of actions that could be taken in an attempt to achieve the objectives described earlier. It is worth noting that these actions are not mutually exclusive; indeed, a full strategy may involve deploying these actions in combination.

Federal and State agencies have a variety of mechanisms by which they may implement mitigation strategies. These mechanisms may come in the form of regulations, guidance, directives, conditions of funding, or permission.

- Various agencies have authority to issue permits (for example, for the take or harassment of Federally Threatened or Endangered bat species, to conduct research on bats, for research activities on National Wildlife Refuges and National Forests, for wildlife holding, for scientific take, for school programs and citizen scientists, for wildlife control operators, and to operate wildlife rehabilitation centers). Agencies may reject or rescind permission for activities that involve handling or proximity to bats or bat habitats. Additionally, permission may be granted so long as a permittee takes a set of risk-mitigation actions (for example,

from the list below). Permittees include university, tribal, Federal, and State agency researchers; environmental consultants; wildlife rehabilitators; and wildlife control operators.

- Multiple agencies (USGS, FWS, NPS, USFS) have Institutional Animal Care and Use Committees, institutional biosafety committees, and other research approval processes (for example, study plan review and approval) or benefit from these committees housed with non-governmental institutions (universities, professional societies, non-governmental organizations); the committees may compel researchers to comply with risk-mitigation measures as they apply to animal welfare concerns. These committees may suspend animal research that has received prior approval until risk mitigation measures germane to animal welfare are adopted.

- Agencies (for example, USGS science centers and Cooperative Research Units, FWS-WNS National Program, NPS visitor contact, and USFS) may issue guidance outlining voluntary measures, which differs from a permit in that the guidance is not compulsory. Agencies may issue guidance and provide training of wildlife rehabilitation and nuisance animal control entities to promote the adherence to best practices.

Potential mitigation actions may reduce the frequency of contact or the probability of transmission of SARS-CoV-2 from infected humans to susceptible bats or change the behavior of individuals interacting with bat populations.

1. The use of PPE, including appropriate N95 respirators or other face masks or shields, eye protection, latex or nitrile gloves, or dedicated clothing (for example, coveralls, Tyvek) to minimize exposure of bats from COVID-19-infected individuals may be required (for example, via agency permit, occupational safety and health programs, or IACUC).

2. Decontamination protocols, such as those provided by the National WNS Response Team to reduce the threat posed by the fungal pathogen *Pseudogymnoascus destructans*, may include best-practice protocols for disinfection of persons and equipment prior to and after handling bats or interacting with bat habitats.

3. Various agencies (for example, States, NPS, Association of Fish and Wildlife Agencies [AFWA], FWS-WNS National program, USFS) have avenues for public outreach, which are already in use to improve public understanding and tolerance of bats, and can be used to encourage the public to engage in behavior and adopt protective measures (including the use of PPE and distancing between humans and bats) to reduce the risk of transmission of SARS-CoV-2 to bats. In some circumstances, this public outreach is coordinated with State and local public health agencies or the CDC.

4. Land managers, including NPS, FWS, USFS, States, and tribes may suspend or limit access to bat populations or habitats. This may involve suspending group tours to caves and access to National Wildlife Refuges or requiring or encouraging distancing from bats. This may also involve directing permittees and agency personnel to delay or suspend some kinds of (non-essential) research.

5. Nuisance animal control activities (undertaken by wildlife control operators [WCO], which may include such activities as capturing individual bats in a home, trapping and transporting bats in an attic, and installing an exclusion device to restrict bat access to human dwellings) could be legally limited to currently established best management practices, which prevent the unnecessary human-bat interactions that are characteristic of less effective approaches. WCOs could be advised or required to not release hand-captured bats.

6. Wildlife rehabilitators may be instructed to avoid accepting bats for rehabilitation.

7. Wildlife rehabilitators may be instructed to not release captive bats or to suspend wildlife rehabilitation of bats. As appropriate testing becomes available, bats might only be released after testing negative for coronavirus.

8. Agencies may issue guidance or directives governing conditions for workers coming into contact with bats, such as a minimum amount of time (for example, 2 weeks) after any potential exposure to SARS-CoV-2, a negative test for active coronavirus infection, a positive serological test, or vaccination to SARS-CoV-2 (when it is available).

9. Agencies, universities, and non-governmental organizations (NGOs) may begin research projects on the risks of SARS-CoV-2 transmission between humans and bats and the effectiveness of potential mitigation options.

10. In the long term, if SARS-CoV-2 does become established in North American bat populations, there might be mitigation measures designed to prevent the virus from moving back to humans, wildlife, or domesticated animals. These may differ from actions identified above.

Causal Linkages between Actions and Objectives

An influence diagram is a graphical representation of a system. The influence diagram in figure 1 describes the causal chains—pathways within the human-bat system—that link the mitigation actions with the desired outcomes. Each arrow represents a process, which is governed by a parameter that describes the effect of an action on an outcome. Figure 1 shows the proposed causal linkages between the potential mitigation actions (orange rectangles) and the long-term objectives

(blue hexagons) described above. Key system states are represented as nodes in the diagram (green ovals).

The central causal logic that is motivating discussions about SARS-CoV-2 in North American bats can be described with three phases: (1) direct or indirect transmission of SARS-CoV-2 from a human to individual wild bats (dashed portion of fig. 1); (2) following this initial transmission, sustained bat-to-bat transmission of SARS-CoV-2, resulting in endemic disease within one or more bat populations (arrow labelled "Sustained bat-to-bat transmission" in fig. 1); and (3) ensuing consequences of endemic SARS-CoV-2 in bats, such as transmission to humans, other wildlife, or domesticated animals (arrows to hexagons in fig. 1). The influence diagram captures the expectation that many of the actions designed to mitigate the risks posed by SARS-CoV-2 have consequences to other important outcomes. The choice of mitigation measures may require decision makers to balance trade-offs among multiple objectives.

Some of the parameters underlying the central steps in figure 1 are transmission parameters (between humans and bats, among bats, between bats and other species, among locations, and between bats and humans) and bat mortality parameters. Mitigation actions are expected to affect the transmission rates, which may subsequently affect the bat mortality rates; we did not consider any actions that address bat mortality rates directly. We recognize that there is likely some background level of transmission (through the general public node, and possibly through a feral/domestic cat node) that may not be affected by any of the mitigation actions considered.

To estimate the consequences of a set of potential mitigation strategies (combinations of the 10 actions described above), we need estimates of parameter values for many of the arrows in the influence diagram (fig. 1). Given the novelty of SARS-CoV-2, there is a lack of robust scientific information for many of these parameters at this time. Values for the parameters may be borrowed from similar systems reported in the scientific literature, but the manner in which these are applied to North American bat populations requires expert judgment.

This influence diagram helps to identify the key parameters for which we require quantitative estimates to calculate the resulting risk, given the selection of a mitigation strategy (that is, one or more actions). In this first phase, we primarily focus on estimating the risk of transmission to bat populations via direct contact with humans (fig. 2), particularly during the time of year when bats are most active and may be in contact with the most humans, which are in the midst of the COVID-19 pandemic (2020). If it is possible to prevent the initial transmission, then all the later steps in the causal pathway are blocked. Further, even if transmission cannot be entirely prevented (for example, because of other pathways of transmission), the reduction in the magnitude of transmission may decrease the risks associated with later steps. We recognized the need to estimate the probability of sustained bat-to-bat transmission. This step is critical to many of the later consequences, so if that risk is very low, the need for mitigation might be less urgent.

The dynamics of initial transmission, although a portion of the larger picture, are nevertheless sufficiently complicated for the first step of our risk analysis. Key factors to consider include potential differences among bat species, regions, and initial population status (including population size and the occurrence of *Pseudogymnoascus destructans* and WNS); differences among the routes of transmission; and differences among the mitigation actions (for example, using PPE in research settings may include appropriate N95 respirators or less protective masks).

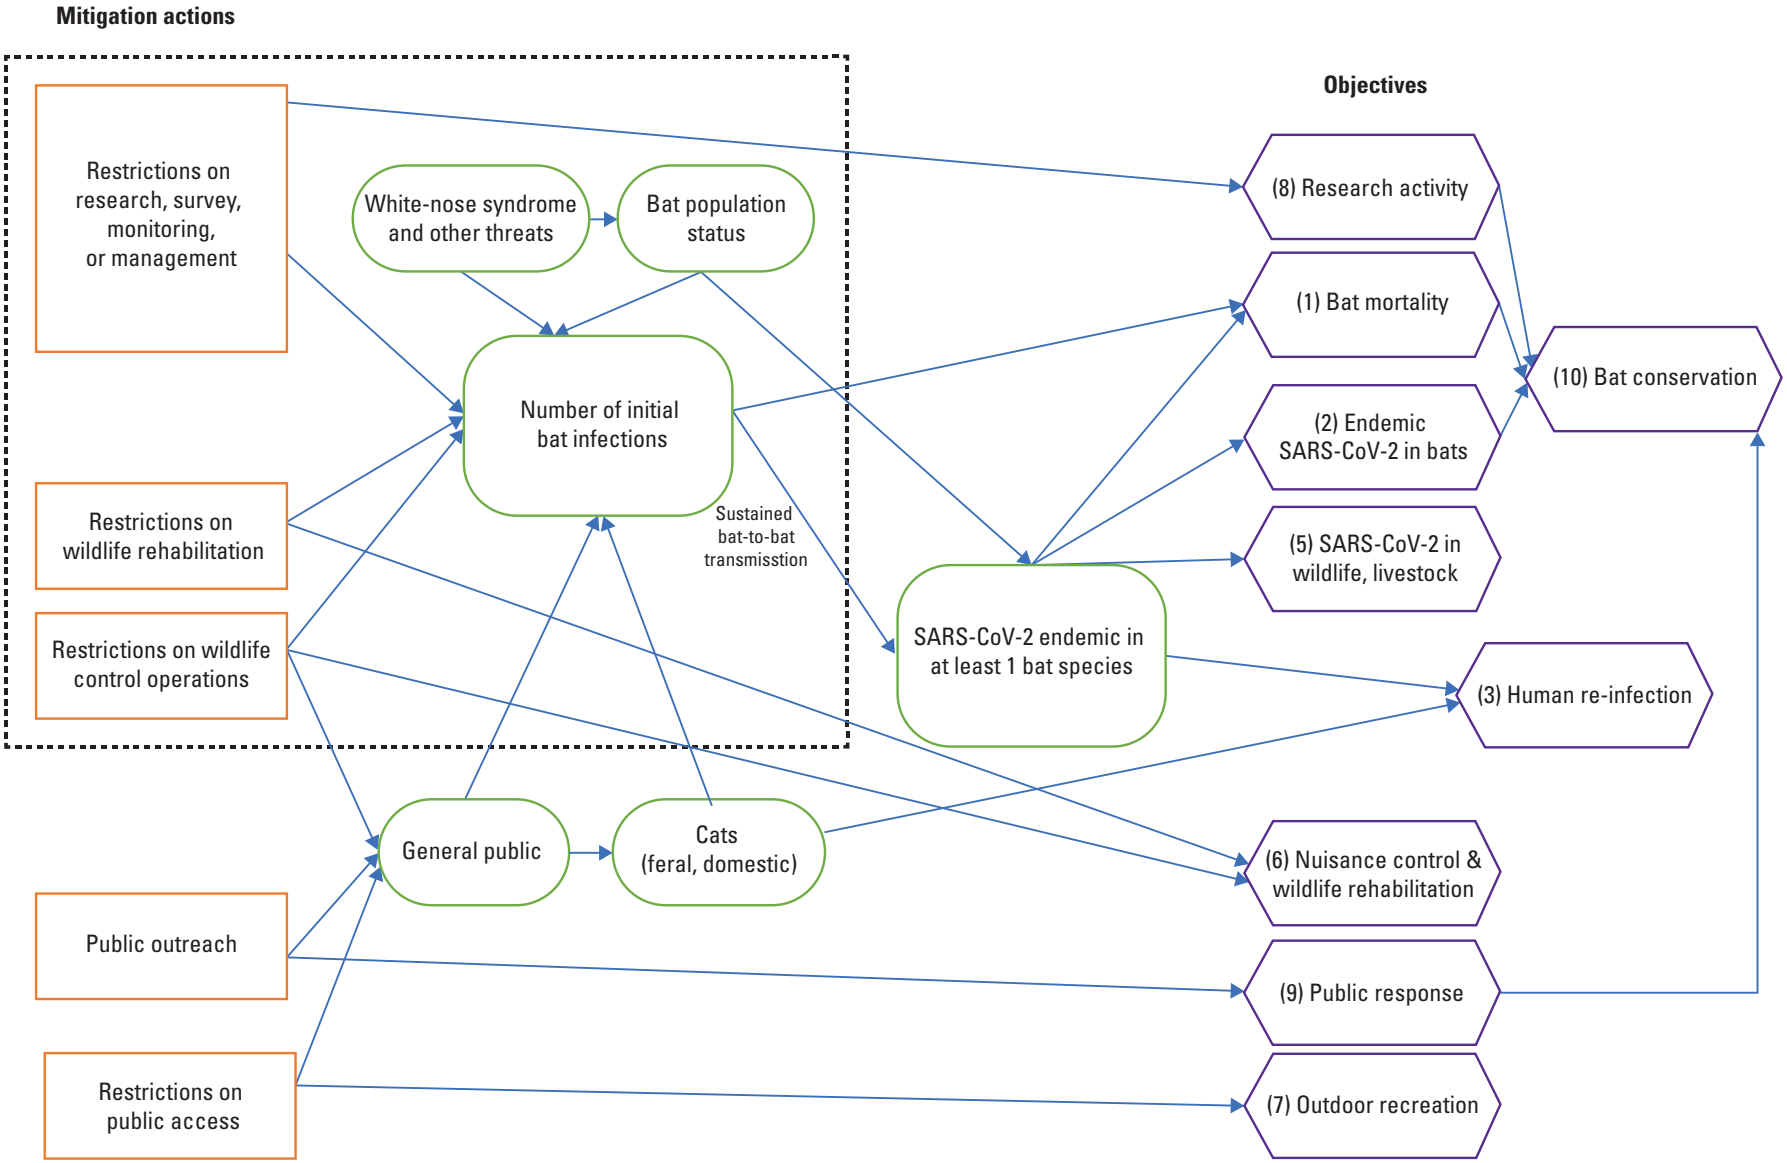

Figure 1. The causal linkages between actions and outcomes motivated by the risk of SARS-CoV-2 entering North American bat populations. The diagram includes potential mitigation actions (orange rectangles), key system states (green ovals), and long-term objectives (blue hexagons). The numbering of the objectives corresponds to the numbering in the "Management Objectives" section of this report. The portion of the diagram within the dashed line emphasizes the initial transmission dynamics analyzed in this assessment.

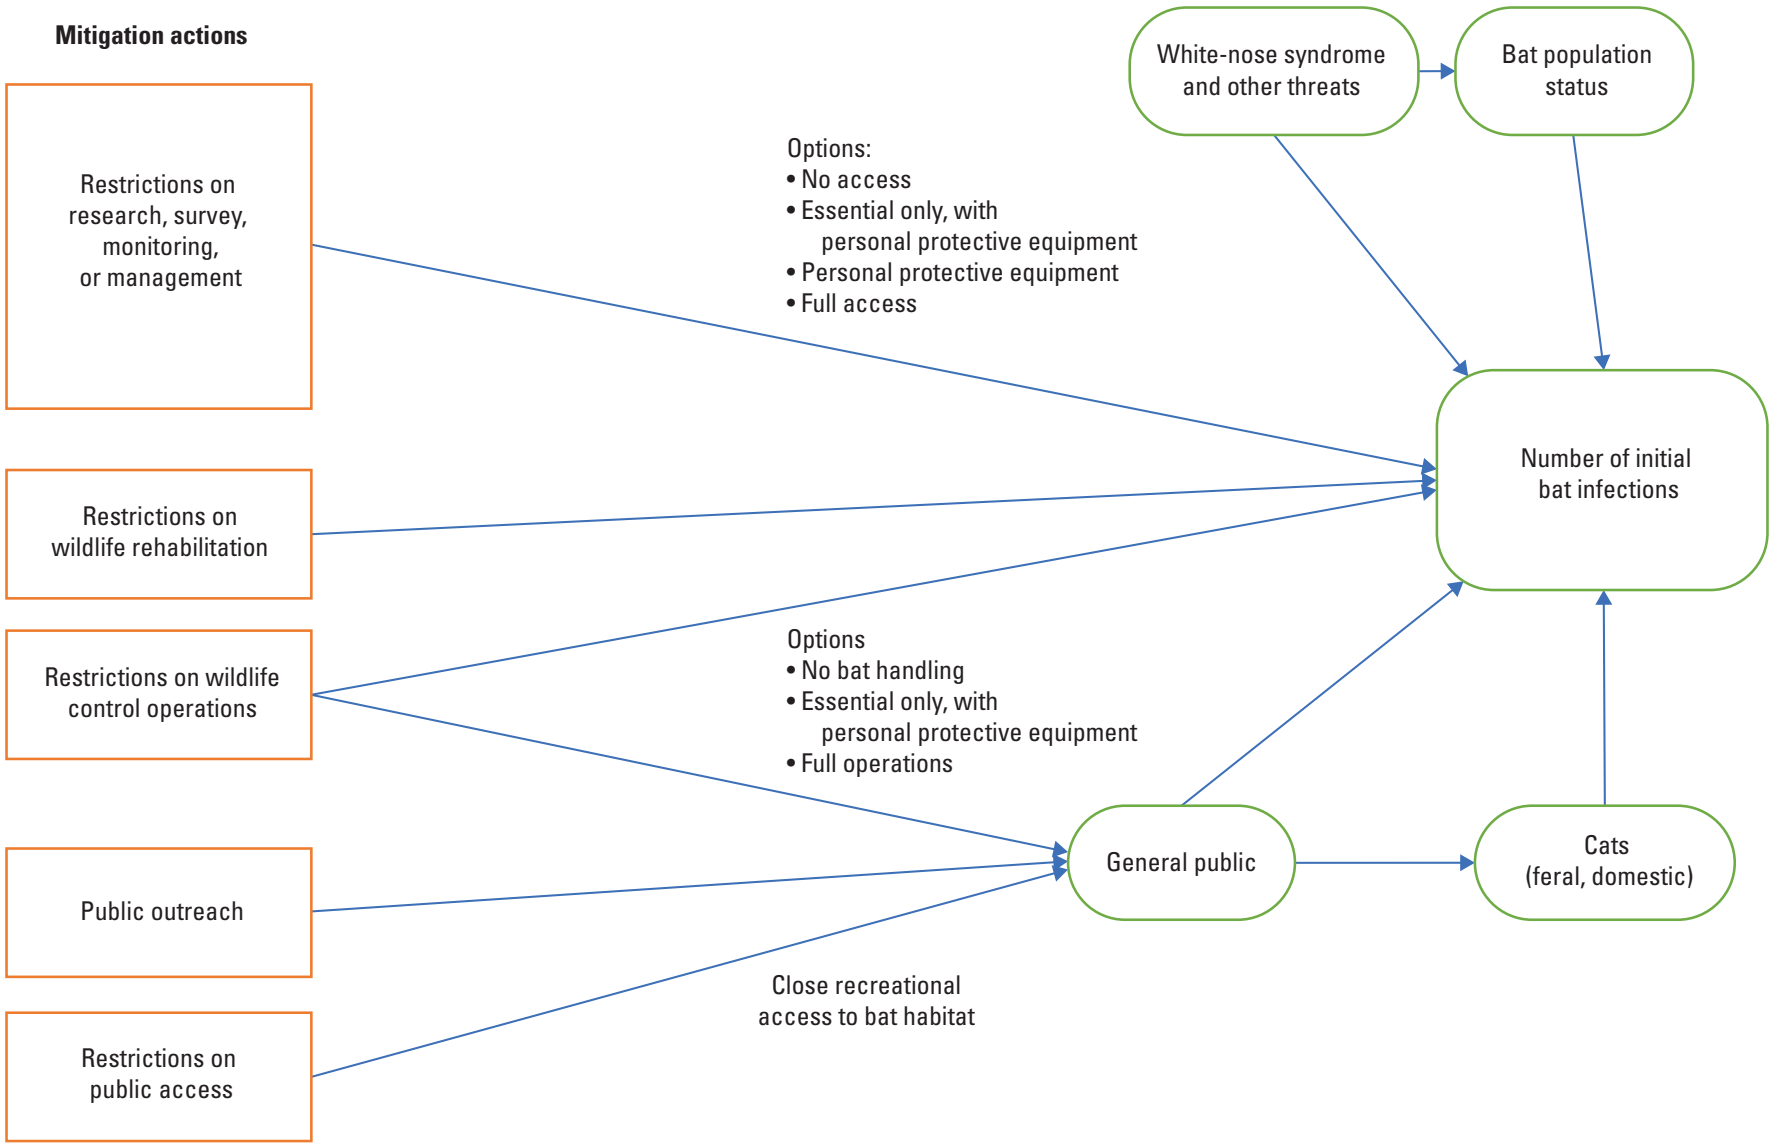

Figure 2. The part of the influence diagram that focuses on the routes of initial transmission of SARS-CoV-2 from humans to bats, with different levels of potential mitigation strategies.

Focal Questions

For this initial risk assessment, we wanted to answer the following five questions, recognizing that they are only a small subset of all the questions embedded in figure 1. These initial questions focus on the transmission risk from humans to bats and begin to address the likelihood of sustained transmission in bats. As a starting point, we chose the little brown bat as a surrogate for North American bats because of their widespread distribution (most of the United States north of Arizona, New Mexico, Texas, and Louisiana, and most of Canada south of the Northwest Territories and Nunavut) and frequent contact with humans (Fenton and Barclay, 1980). We chose to focus on the transmission pathways that may be directly affected by guidance from wildlife and research agencies. Finally, we chose to focus our assessment of risk over the near term (that is, the next 6 months), between April and the end of the 2020 bat active season (November, the beginning of hibernation). The five questions below focus on the baseline probability of transmission and the potential effect of mitigation strategies on the transmission probability. In later sections, we use these questions to motivate a mathematical model, then to develop methods, including expert elicitation, to estimate the relevant parameters.

1. Thinking specifically about little brown bats throughout their range in North America, how many individual wild bats would be infected by SARS-CoV-2 directly from humans undertaking research, survey, monitoring, or management (RSM) activities between now (April 2020) and the initiation of hibernation in autumn 2020, in the absence of any new restrictions, regulations, or protocols?

2. Thinking specifically about little brown bats throughout their range in North America, how many individual bats would be infected by SARS-CoV-2 and released into the wild by humans engaged in wildlife rehabilitation (WR) between now (April 2020) and the initiation of hibernation in autumn 2020, in the absence of any new restrictions, regulations, or protocols?

3. Thinking specifically about little brown bats throughout their range in North America, how many individual wild bats would be infected by SARS-CoV-2 directly by humans engaged in wildlife control (WC) between now (April 2020) and the initiation of hibernation in autumn 2020, in the absence of any new restrictions, regulations, or protocols?

4. (a) How much might the transmission risk owing to research, survey, monitoring, and management (Question 1) be reduced if the fieldwork protocols and guidance included all the following:

   - restriction of fieldwork to people without symptoms or contact with someone who had symptoms of COVID-19 in the last 14 days,
   - training and oversight in the proper use of PPE,
   - proper use of Tyvek or other dedicated clothing,
   - proper use of an appropriate N95 respirator, and
   - proper use of gloves when handling bats.

   (b) Is there any reason to believe this reduction in transmission risk owing to proper use of PPE would be different for wildlife rehabilitators or wildlife control operators compared to scientists or biologists engaged in research, survey, monitoring, and management?

5. What is the basic reproduction number, R_0, for SARS-CoV-2 in little brown bats during the active season? That is, for each infected little brown bat within a naïve population, how many other little brown bats would become infected with the virus?

Questions 1–3 are designed to estimate the probability of infection of bats with SARS-CoV-2 via three pathways of exposure (research and management, wildlife rehabilitation, and wildlife control operations), in the absence of any new guidance (status quo). Question 4 addresses the efficacy of PPE to reduce exposure and subsequent infection. Question 5 provides a rough estimate of the likelihood of sustained bat-to-bat transmission.

This initial focus leaves out many questions of interest. It does not address indirect pathways of transmission (for example, via the general public's contact with bats in their homes or during recreation, or via domestic and feral cats). The initial focus here is on pathways that State and Federal wildlife agencies may be able to directly interrupt. Likewise, this initial focus does not address the effects on the other fundamental outcomes of interest (including mortality of bats, transfer back to humans; fig. 1), but it does address the primary node through which the risk flows (exposure and infection of bats from humans). Because of the urgency to consider interventions available to management agencies in preventing transmission of SARS-CoV-2 from humans to bats, the focus of this assessment is on the pathways that can be affected in the near term.

Model for the Direct Transmission Pathways

The first three questions listed above address three transmission pathways. Because the pathways are fairly complex, we believed that it would be difficult for experts to directly answer Questions 1–3. Instead, for these questions, we have developed a mathematical model for the component elements of the pathways, and we focused elicitation on those elements.

For the first pathway, we consider the following model, which describes individual components of the transmission process from humans engaged in research, survey, monitoring, or management of bat populations. The model combines the average infection status of humans working with bats, the number of bats encountered (directly through handling and

indirectly by proximity), the probability of exposing the bats to the virus, and the probability a bat can be infected once it is exposed:

$$I_{ML}^{RSM} = p_{RSM}^{+}(H_{ML}^{RSM}\beta_{H}^{RSM} + E_{ML}^{RSM}\beta_{E}^{RSM} + P_{ML}^{RSM}\beta_{P}^{RSM})\sigma_{ML} \quad (1)$$

where

I_{ML}^{RSM} is the number of little brown bats (ML) directly infected over the course of the 2020 active season by people engaged in research, survey, monitoring, or management (RSM);

p_{RSM}^{+} is the probability that someone conducting such work is actively shedding SARS-CoV-2 virus on any given day of the 2020 active season;

H_{ML}^{RSM} is the total number of little brown bats physically handled by any RSM scientist over the course of the 2020 active season;

β_{H}^{RSM} is the probability that a bat handled by an RSM scientist who was actively shedding virus would be exposed to the virus (an "exposure probability"), in the absence of any new restrictions, regulations, or protocols, taking into account the handling time typical of RSM activities;

E_{ML}^{RSM} is the total number of little brown bats encountered by any RSM scientist within a 6-foot proximity in an enclosed space (such as a cave or attic), without handling, over the course of the 2020 active season;

β_{E}^{RSM} is the probability that a bat in an enclosed space within a 6-foot proximity of (but not handled by) a RSM scientist who was actively shedding virus would be exposed to the virus (an "exposure probability"), in the absence of any new restrictions, regulations, or protocols;

P_{ML}^{RSM} is the total number of little brown bats encountered by any RSM scientist within a 6-foot proximity but **not** in an enclosed space, without handling, over the course of the 2020 active season;

β_{P}^{RSM} is the probability that a bat **not** in an enclosed space but within a 6-foot proximity of (and not handled by) an RSM scientist who was actively shedding virus would be exposed to the virus (an "exposure probability"), in the absence of new restrictions, regulations, or protocols; and

σ_{ML} is the probability that a little brown bat exposed to a sufficient viral dose of SARS-CoV-2 would actually become infected by the virus (the "infection probability").

Note that we are separating the processes of exposure and infection. By exposure probability, we mean the likelihood that a particular interaction between an average bat and a person who is actively shedding SARS-CoV-2 virus will result in exposure of the bat to a sufficient viral dose to cause infection. By infection probability, we mean the probability that the virus replicates in the host (bat) tissue, conditional on that bat having been exposed to a sufficient viral dose. That is, the exposure process is about whether enough virus was transferred to make an infection possible; it is a property of the interaction between the biologist and that bat. The infection process is about the molecular, cellular, immunological, and physiological conditions that allow viral replication in the bat; it is a property of the interaction of the bat and the pathogen.

The parameters H_{ML}^{RSM}, E_{ML}^{RSM}, and P_{ML}^{RSM} were estimated by surveying State, Federal, and research agencies engaged in bat research (see "Methods" section). The parameter p_{RSM}^{+} was estimated from human epidemiological models of COVID-19, accounting for the expected cumulative incidence over the 2020 active season and the average length of time that an infected person is shedding virus (see "Methods" section). At this time, in the absence of empirical data, the three exposure probabilities, β_{H}^{RSM}, β_{E}^{RSM}, and β_{P}^{RSM}, and the infection probability, σ_{ML}, had to be estimated through expert elicitation.

We describe the second pathway of transmission, through the activities of wildlife rehabilitators, in a similar manner:

$$I_{ML}^{WR} = p_{WR}^{+}(H_{ML}^{WR}\beta_{H}^{WR} + P_{ML}^{WR}\beta_{P}^{WR})\sigma_{ML} \quad (2)$$

where the subscripts and superscripts now refer to people engaged in wildlife rehabilitation (WR), but the parameters are analogous to equation 1. Note that in this equation, there are only two "distances" of interaction: handling (*H*) and proximity (*P*, here meaning within a 6-foot proximity, whether enclosed or not); we expect that, in most cases, the interactions that wildlife rehabilitators have with bats involve handling, typically for more extensive periods of time than in other pathways.

The parameters H_{ML}^{WR} and P_{ML}^{WR} were estimated by surveying State agencies that permit or otherwise authorize wildlife rehabilitation organizations (see "Methods" section). At this time, the two exposure rates, β_{H}^{WR} and β_{P}^{WR}, were estimated through expert elicitation because we lack empirical estimates.

We assumed that the parameter p_{WR}^{+} did not differ from p_{RSM}^{+}. Likewise, we assumed the infection rate conditional on exposure, σ_{ML}, is the same in equations 1 and 2, as well as equation 3 below. That is, we assumed the infection rate is a function of the bat species but does not differ on the basis of the route of transmission because the effects of the route of transmission are captured in the exposure rates.

We describe the third pathway of transmission, through the activities of wildlife control operators, in a similar manner:

$$I_{ML}^{WC} = p_{WC}^{+}(H_{ML}^{WC}\beta_{H}^{WC} + P_{ML}^{WC}\beta_{P}^{WC})\sigma_{ML} \quad (3)$$

where the subscripts and superscripts now refer to people engaged in wildlife control operations (WC), but the parameters are analogous to those in equation 2.

The parameters H_{ML}^{WC} and P_{ML}^{WC} were estimated by surveying State agencies that permit or otherwise authorize wildlife rehabilitation organizations (see "Methods" section). The two exposure rates, β_H^{WC} and β_P^{WC}, were estimated through expert elicitation. As in equation 2, we assume that p_{WC}^{+} is identical to p_{RSM}^{+} and that σ_{ML} is the same across transmission pathways.

Equations 1, 2, and 3 specifically focus on the transmission rates under status quo conditions, by which we mean the ways wildlife biologists and other professionals in the United States most likely would have interacted with bats prior to the arrival of SARS-CoV-2 in North America. In particular, past concern about transfer of biological agents was primarily focused on rabies virus, histoplasmosis, and the fungus *P. destructans*. Typical protocols for *P. destructans* involve decontamination of clothing and footwear between sites and wearing nitrile gloves (with disposal or decontamination between bats), but use of face masks or respirators was not implemented or continued once it was determined humans were unlikely to be harmed by the fungus. Face masks are employed only in specific situations, primarily when working amidst large amounts of bat guano. We were also interested in assessing whether updating guidance and protocols for work with bats (including use of PPE) can reduce the transmission rates. To do this, we assume that the effect of such guidance is on the exposure parameters (the β parameters). For this initial risk assessment, we focus on guidance that allows all work with bats to continue but includes all of the mitigations described in Focal Question 4. We estimated the change in the β parameters as a result of use of enhanced PPE through expert elicitation.

Methods

Expert Elicitation

We used expert elicitation methods to estimate 12 parameters for which data are not yet available (the seven exposure rates in equations 1, 2, and 3; the infection rate in equations 1, 2, and 3; three multipliers of exposure rate that reflect the effect of enhanced PPE; and the basic reproduction number, R_0, for SARS-CoV-2 in little brown bats; see appendix 1). To reduce the effects of expert bias and overconfidence on the results, we conducted an elicitation using a modified Delphi process that includes two rounds of elicitation with feedback and discussion in between. Six steps were followed: (1) choosing experts, (2) training experts, (3) conducting a first round of elicitation, (4) reviewing and discussing the first round with the experts, (5) allowing experts to adjust their assessments in a second round of elicitation, and (6) aggregating the estimates across experts (Hanea and others, 2017). The modified Delphi approach requires experts to share and discuss the logic behind their opinions. In addition, to capture within-expert uncertainty, the four-point elicitation procedure was used (Speirs-Bridge and others, 2010), which consists of asking experts for their lowest, highest, and best estimates, and their confidence the true value lies within the reported interval. By using the scientific judgments from multiple experts, we included uncertainty in scientific understanding in the predictions of the effect of mitigation actions on the desired outcomes.

Through literature review and the professional contacts of two of the authors of this report (P.M. Cryan and K.J. Olival), a list was compiled of 43 experts whose expertise spans bat ecology, virology (especially of coronaviruses), epidemiology, and wildlife disease, with an emphasis on experts who had a demonstrated background in one or more of those fields. Seventeen experts from this list were invited to participate in the elicitation. The invited participants were selected to produce a group with diverse and complementary scientific backgrounds, from several countries, with a balanced gender representation. The invited participants included scientists from academic institutions, government agencies, and non-governmental organizations (see Acknowledgments).

Training

Formal expert elicitation is a new process for many, so the first step was to familiarize experts with the approach. This training step increases the quality of expert judgment for unknown qualities (Cooke, 1991). Before starting the elicitation concerning the questions of interest, we provided the expert panel a chance to practice the elicitation methods. Questions were provided for which the answers were known (that is, answers were identified values from the literature, but they were unlikely to be known precisely by experts). The questions were used to ensure that the instructions were understood by the experts and to allow the experts a chance to self-calibrate their estimates of uncertainty. We asked three questions (Appendix 1)—one for which we assumed the uncertainty had a normal distribution (forearm length of a little brown bat), one for which we assumed a log-normal distribution of uncertainty (R_0 of WNS), and one for which we assumed a logit-normal distribution (breeding probability)—which represented the kinds of parameters we would ask in the real elicitation. Experts were provided with a custom spreadsheet to record their answers, which plotted the probability distribution resulting from their responses. We did not use responses to the training questions to rank expert quality or weight experts when summarizing responses for the model.

The results of the training questions were summarized and sent to the experts prior to the first elicitation round. The exercise revealed some potential for linguistic uncertainty in two of the questions (R_0 and breeding probability), which we discussed in feedback to the experts prior to the first elicitation round.

Round 1

The experts were provided with a document that described the background of the study, a summary (a draft synthesis manuscript, including literature references) of the current state of knowledge on SARS-CoV-2 and bats, a detailed description of the quantities that were being elicited (see Appendix 1), instructions for completing the elicitation, and a spreadsheet that plotted the distribution that represented their uncertainty from their responses to the four-point elicitation. The experts were asked to work independently and return their responses within about 72 hours.

Group Discussion

The results from the first round of elicitation were compiled; for each question, the anonymous responses for each of the experts were shown graphically (for example, appendix fig. 2.1*A*), the fitted distribution for each expert was plotted (for example, fig. 2.1*B*), and the average distribution across experts was plotted (for example, fig. 2.1*C*). Two 2-hour video conference calls were held with the experts to discuss the first round of results, focusing on several topics: clarifying the interpretation of the questions, sharing insights of individual experts, discussing notable differences in how the experts answered the questions, and reinforcing the instructions for the four-point elicitation method. After the calls, the results of the first round and a brief written summary of the discussion (especially, to clarify the questions) were provided to the experts.

Round 2

The experts were asked to reconsider their responses to the questions, taking into account the group discussion, and independently provide a revised set of answers within 24 hours.

Aggregation of Experts

Separately for each parameter and expert, we fitted a probability distribution to the responses to the four-point elicitation, assuming the best estimate corresponded to the median and the confidence limits represented symmetric quantiles. We assumed that questions 1–8 were best represented with logit-normal distributions because the quantities elicited were proportions bounded by 0 and 1, which is the support for the logit-normal distribution. We assumed that questions 9–11 and 13 were best represented with lognormal distributions because the quantities elicited were bounded by 0 on the lower end and unbounded on the upper end, like the lognormal distribution. We fitted the distributions by regressing the inverse cumulative distribution function of the quantiles against the corresponding values.

The individual probability density functions (PDF) were aggregated, with equal weight, across experts. We then found the parameters of a logit-normal or lognormal distribution that best fit the average PDF, as measured by the Kullback-Leibler distance (Kullback and Leibler, 1951). The fitted, aggregated distribution provided an estimate, with uncertainty, for each parameter.

Other Parameters

Bat Handling Data

Seven State and four Federal wildlife agencies were queried for bat research or permit records to estimate the number of bats handled over the course of a field season for the three transmission pathways. The State and Federal agencies queried were a non-random sample, composed primarily of agencies that were on the guidance committee (see Acknowledgments).

Probability an Individual Human is Shedding SARS-CoV-2

To estimate the probability that a bat worker would be shedding SARS-CoV-2 at the time of an encounter with a bat (p^{+}_{RSM} in equation 1), three components were considered: cumulative incidence, which is the probability of the worker becoming infected with SARS-CoV-2 in the United States from April 15 through November 15, 2020 (C^{+}); the length of time an individual with COVID-19 is shedding virus (s); and the length of the period of time in question (t, 214 days, April 15–November 15, 2020). Then, the desired probability is given by

$$p^{+}_{RSM} = C^{+} * \frac{s}{t}. \quad (4)$$

Regarding the cumulative incidence (C^{+}), although a number of models can forecast SARS-CoV-2 infection in humans, most report only the peak number of hospital admissions and intensive care unit beds or provide forecasts for only the next approximately 4 months. We could not find any models that specifically forecast the cumulative incidence between April 15 and November 15, 2020, but there are a few models that forecast the incidence through the course of the epidemic. If we assume that the bulk of the epidemic in the United States will occur by November 15, those forecasts are helpful benchmarks. The forecast of Moghadas and others (2020) was used, which estimates the cumulative incidence for the COVID-19 epidemic in the United States under two values of R_0 for SARS-CoV-2 in humans (2.0, 2.5), resulting in 177 million and 233 million people infected through the end of the epidemic (representing 53.8 and 70.5 percent, respectively, of the total U.S. population infected, assuming a U.S. population

size of 329.1 million, https://www.census.gov/popclock/; accessed April 20, 2020). These estimates are similar to the forecast of Ferguson and others (2020) for 81 percent of the U.S. population to be infected, if R_0 is 2.4. We treated the two estimates from Moghades and others (2020) as the median and 90th quantile of a logit-normal distribution. For the 10th quantile for the cumulative incidence of COVID-19 disease in the United States by November 15, 2020, we divided the number of reported cases on April 20 (788,172; https://www.cdc.gov/coronavirus/2019-ncov/cases-updates/cases-in-us.html) by a reporting rate of 0.066 for the United States (Bommer and Vollmer, 2020) and multiplied by 3 (assuming mid-April was roughly the peak infection rate in the United States, and the decline will involve three times as many cases as the increase); the result is a 10.9-percent cumulative infection rate through November 15. We fitted these three quantiles (10th, 50th, and 90th) to a logit-normal distribution.

We estimated shedding duration (s) using results from Zhou and others (2020a) who found a median duration of SARS-CoV-2 shedding for hospitalized patients to be 31.0 days from illness onset (interquartile range [IQR]: 24.0–40.0, minimum: 18, maximum: 48). Other studies (Wölfel and others, 2020; Zou and others, 2020) report shorter maximum durations, but that may be related to the lengths of observation studies. A linear model fitted to figure 1b of Wölfel and others (2020) estimates a maximum of 25 days of shedding. Zou and others (2020) report detection of viral DNA up to the end of the study period (21 days). To capture uncertainty in the duration of viral shedding, we fitted a normal distribution to the values (18, 31, 48), associating those values with three quantiles (0.025, 0.50, 0.975).

Simulation Model

To integrate the estimates of the parameters in equations 1, 2, and 3, and to propagate the uncertainty in those estimates through to the results, we built a Monte Carlo simulation model for those equations. We sampled each parameter from the probability distribution that represented its estimate. In most cases, the parameters were sampled independently, but for the 3 RSM exposure probabilities (the β parameters in equation 1), the 2 WR exposure probabilities (the β parameters in equation 2), the 2 WC exposure probabilities (the β parameters in equation 3), and the three PPE multipliers, we assumed that the parameters in those sets had a correlation of 0.50 to reflect the assumption that, for example, if the true exposure probability for RSM handling was on the high end of its uncertainty distribution, the true exposure probability for RSM proximity is likely to be at the high end of its uncertainty distribution. For each of 1,000 replicates in the simulation, equations 1 through 3 were used to calculate the number of infected bats from the sampled parameter values.

Results

Encounters with Bats

Federal and State wildlife agencies do not have a common system for documenting and recording encounters with bats by scientists, rehabilitators, and wildlife control operators, so the data on encounters were difficult to compare across agencies (table 1). Bat research, survey, monitoring, and management activities span all three types of encounter, with a mixture that depends on how the agency in question permits such activities, as well as the needs of the specific setting. Across agencies that were able to report encounters for all three modes, 45.8 percent involved handling, 11.5 percent involved proximity in an enclosed space, and 42.7 percent involved proximity in an unenclosed space. Wildlife rehabilitation invariably involves handling, not simply proximity to bats. Wildlife control operations have a mixture of activities that involve handling or proximity. Across the States that reported totals for two modes of encounter, 22.9 percent of the encounters by wildlife control operators involved handling, and 77.1 percent involved proximity without handling.

After the data in table 1 were collected from the wildlife agencies, we realized several unanticipated challenges: (1) the data are not collected in a common way across agencies, making comparisons difficult; (2) there may be duplicate counts because the same activity may be recorded by multiple agencies (for example, a research project conducted on USFS land in Virginia may be recorded both by USFS and by the Virginia Department of Game and Inland Fisheries); (3) it was not possible, in the available time frame, to gather comprehensive data across the United States; and (4) in many cases, the data on encounters are recorded for all bats, not by species. In light of these challenges, we were not able to estimate the H, E, and P parameters in equations 1, 2, and 3. Instead, we used the data in table 1 to estimate relative values for H, E, and P. Thus, in the results that follow, the number of potential infections is not expressed on an absolute scale, but on a relative scale, reflecting the probability of infection.

Expert Judgment

Of the 17 experts invited to participate in the elicitation process, 13 participated in either Round 1 or Round 2; in the final analysis, we included only the 12 experts who had participated in the group discussions and who submitted Round 2 estimates afterwards. The four-point responses, the individual fitted distributions, the mean aggregate distribution, and the fitted aggregate distribution are shown for each question in Appendix 2.

Table 1. Number of bats encountered during the 2019 active bat season.

[The entries show the number of bats of any species encountered during the 2019 active bat season, April 15–November 15, 2019, as reported through direct requests to the agencies listed in the table. Blank entries indicate only that the quantity was not recorded or estimated by the agency, whereas an entry of 0 indicates that the agency recorded no encounters in that category. Gray cells indicate no encounters were expected because the agencies in question do not oversee rehabilitation or wildlife control operations. Total[6]	8,642	2,172	8,056	1,459	0	447	1,502

[1]The large number of bats in the proximity of scientists arises primarily from emergence counts from roost sites.

[2]This estimate includes bats handled by homeowners as well as wildlife control operators.

[3]Includes only wildlife control operators with permits to handle State threatened and endangered species (possibly only 25–30 percent of operators).

[4]This includes bats within 6 feet of tour guides at Mammoth Cave National Park over the duration of the summer.

[5]This includes all USGS scientists within the Ecosystems Mission Area who work on bats.

[6]For all columns within each category (Research, survey, monitoring, and management; Wildlife rehabilitation; Wildlife control), the total includes those agencies that reported entries for each mode of handling in the category, without a noted exception as to how the encounters were interpreted. That is, to be included in the totals for a category, an agency needed to report entries for each of the handling modes, and there needed to be no exceptions noted on any of the entries. If these conditions were not met, then none of the entries for that agency were included in the totals for that category.

For RSM workers, the detailed responses for the three exposure probabilities (Q1, Q2, and Q3) are shown in Appendix figures 2.1, 2.2, and 2.3, and the fitted aggregate distributions are summarized in figure 3. Using the fitted aggregate distribution, we estimated that a median 49.7 bats per 100 handled by actively shedding SARS-Co-V-2 virus (CoV+) RSM workers would be exposed to a sufficient dose of virus for infection (80-percent interval, 15.3–84.3); this is close to a uniform distribution between 0 and 100, indicating the experts had considerable uncertainty about the degree of this exposure. For Q2, the aggregated expert judgment is that a median 19.4 bats per 100 encountered within an enclosed space by CoV+ RSM workers would be exposed to a sufficient dose of virus to possibly lead to infection (80-percent interval, 2.2–72.4). For Q3, the aggregated expert judgment is that a median 6.4 bats per 100 encountered within 6 feet in an unenclosed space by CoV+ RSM workers would be exposed to a sufficient infectious dose of virus (80-percent interval, 0.6–43.8). Thus, although the experts expressed considerable uncertainty in the range of these exposure probabilities, the pattern showed a consistent decrease as the nature of the encounter became less proximal (fig. 3). Similar types of results were estimated for the exposure rates through the wildlife rehabilitation (figs. 2.4 and 2.5) and wildlife control (figs. 2.6 and 2.7) transmission pathways.

Conditional on exposure to a sufficient dose of SARS-CoV-2, the experts estimated that the median probability a little brown bat would develop an infection was 0.44 (80-percent interval, 0.08–0.88; fig. 2.8). During discussion, the experts noted their particular uncertainty about this parameter (represented by the nearly uniform aggregate distribution) and noted that this parameter is a critically important nexus in the causal diagram (fig. 1).

The experts expected that proper use of PPE (that is, an appropriate N95 respirator and other protective gear) would be effective at substantially reducing the exposure probability. The detailed responses of the experts are shown in figures 2.9, 2.10, and 2.11 (Appendix 2) as proportional multipliers on exposure probability. The fitted aggregate distribution, expressed as the percent reduction in exposure (1 minus the quantity elicited), did not differ substantially among the three modes of handling (fig. 4), ranging from a mean of 94 to 96 percent effective. When asked an open-ended question about whether the effectiveness of PPE would differ among scientists (RSM), rehabilitators (WR), and wildlife control operators (WC), the experts were inconclusive; about half thought there would not be tangible differences in the effectiveness of PPE, and the other half thought that differences in compliance among the three groups could possibly affect the amount by which exposure was reduced.

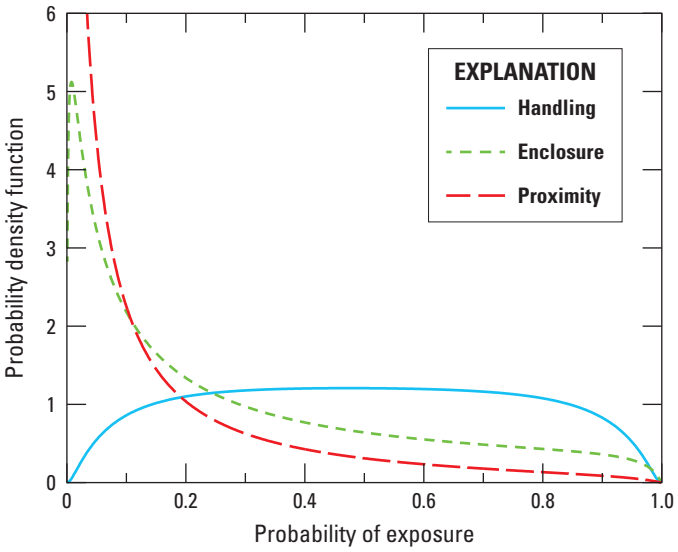

Figure 3. Aggregate probability distributions for the probability of exposure of bats from a SARS-CoV-2-positive research, survey, monitoring, and management worker, referenced in expert judgment questions Q1, Q2, and Q3.

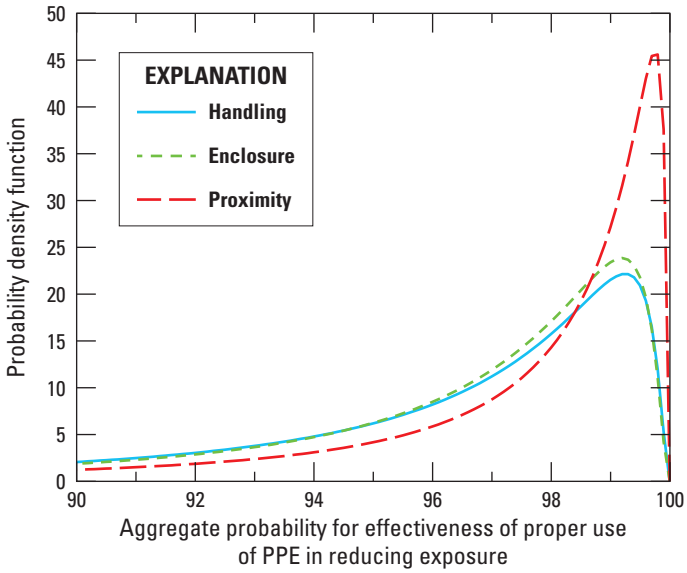

Figure 4. Aggregate probability distributions for the effectiveness of proper use of personal protective equipment in reducing exposure of bats to SARS-CoV-2 by a research, survey, monitoring, and management worker, referenced in expert judgment questions Q9, Q10, and Q11, expressed as the percent reduction in exposure.

Probability a Worker is Shedding Virus

The probability of a worker shedding SARS-CoV-2 virus during an encounter with bats over the course of summer 2020 (April 15–November 15), absent a change in field work practices, was estimated to be 0.057 (that is, 5.7 percent, median; 80-percent interval, 0.022–0.112; fig. 5). This is based on a cumulative incidence of 0.39 (median; 80-percent interval, 0.17–0.71) and a shedding duration of 33 days (median; 80-percent interval, 23–42) within a 214-day field season.

Probability of Bats Being Infected

Combining the probabilities of exposure and infection, for multiple modes of encounter under status quo conditions, we estimate that a CoV+ RSM scientist would infect 107 (median) per 1,000 bats (80-percent interval, 16–348); a CoV+ WR worker would infect 252 (median; 80-percent interval, 41–654) per 1,000; and a CoV+ WC worker would infect 50 (median; 80-percent interval, 5–268) per 1,000 (fig. 6).

Combining the probabilities of exposure and infection (fig. 6) with the probability that a worker is CoV+ (fig. 5),

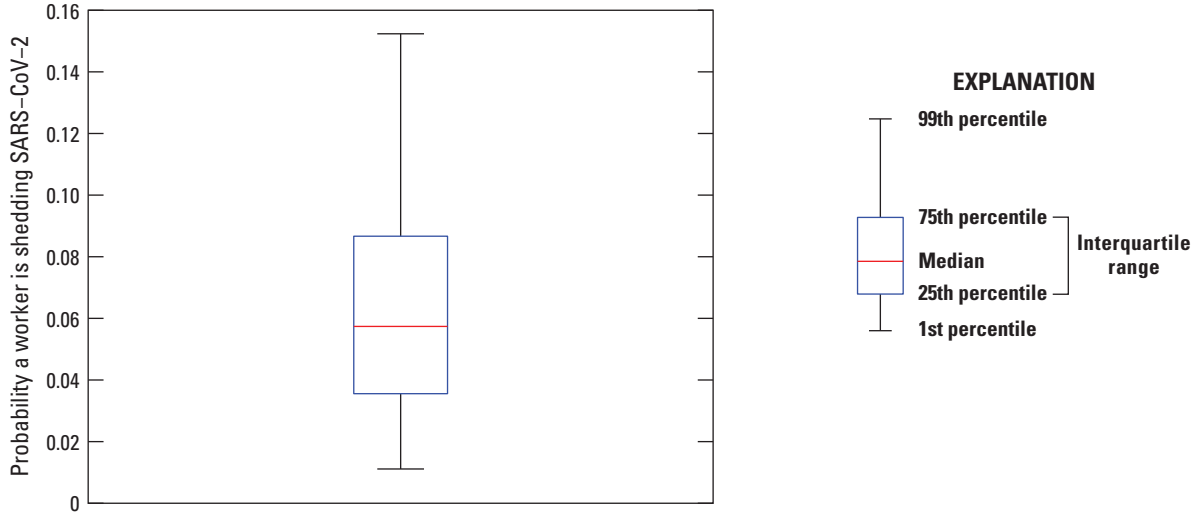

Figure 5. Probability that a worker is shedding SARS-CoV-2 during an encounter with a bat.

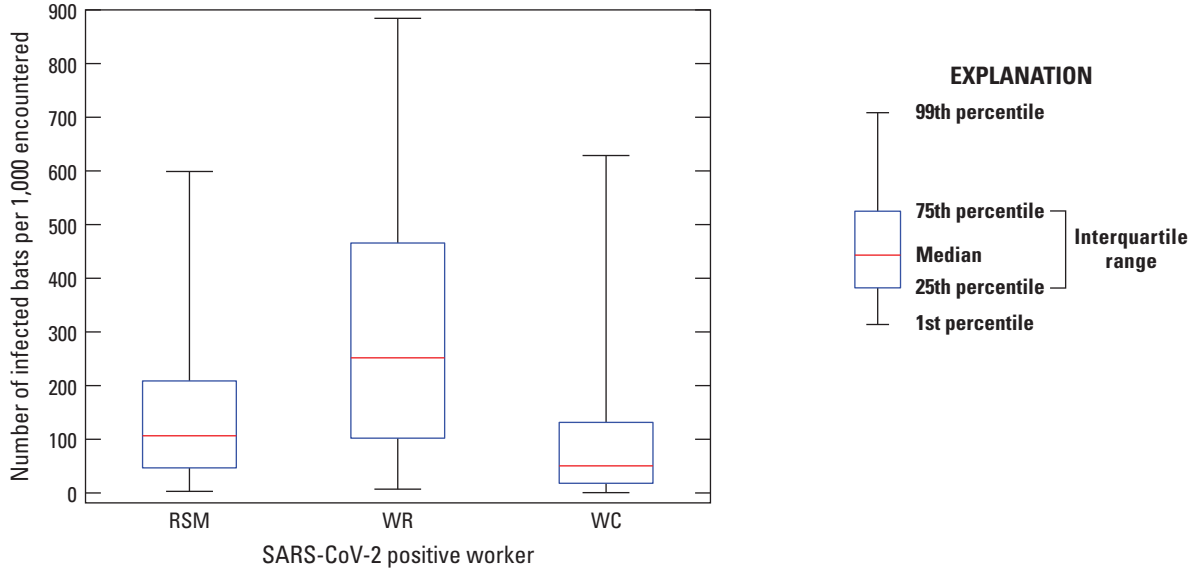

Figure 6. Number of bats per 1,000 exposed to and infected by virus from a SARS-CoV-2-positive worker, by transmission pathway, under status quo working conditions. (RSM, research, survey, monitoring, and management activities; WR, wildlife rehabilitation; WC, wildlife control operations.) These results were obtained with the assumed ratio of encounter modes (handling, enclosure, and proximity) estimated from the totals in table 1.

we estimate that an average RSM worker would infect 6.0 (median) per 1,000 bats (80-percent interval, 0.8–22.2); an average WR worker would infect 12.7 (median; 80-percent interval, 1.8–42.8) per 1,000; and an average WC worker would infect 2.7 (median; 80-percent interval, 0.3–16.6) per 1,000 (fig. 7), under status quo conditions. But if PPE protocols and training are implemented, the respective probabilities of infection drop to 0.2, 0.4, and 0.1 bats per 1,000, respectively (median values, with narrow uncertainty ranges; fig. 7).

Another way to understand the results in figure 7 is to consider the probability that the number of infections exceeds some threshold value. For example, the probabilities that at least 5 per 1,000 bats are infected is 55 percent for RSM (1.3 percent with PPE), 75 percent for WR (4.6 percent with PPE), and 35 percent for WR (0.6 percent with PPE). We use the exceedance threshold 5 per 1,000 to demonstrate this approach; the relevant threshold value reflects the decision maker's risk tolerance for introduction of infected bats to the wild population.

The effect of the mode of encounter on the infection rate in the RSM transmission pathway is notable (fig. 8). The combined probability that at least 5 bats per 1,000 are exposed to and infected by SARS-CoV-2 from an average RSM worker is 66 percent if handling is involved (3.1 percent with PPE), 40 percent if the bats are encountered in an enclosed space without handling (1.3 percent with PPE), and 24 percent if the bats are encountered in an unenclosed space (0.4 percent with PPE).

Probability of Transmission in Bat Populations

The experts expressed considerable uncertainty about the basic reproduction number (R_0) for SARS-CoV-2 in little brown bats (fig. 9; expert panel responses in fig. 2.12). The bulk of the fitted aggregate distribution was less than 1.0, with a median of 0.45 and an 80-percent interval of (0.05, 4.38), but the experts could not rule out the possibility that SARS-CoV-2 could be effectively transmitted in a little brown bat population. For the fitted aggregate distribution, the probability that the basic reproduction number (R_0) is greater than 1 is 32.6 percent.

Discussion

This risk assessment was a response to the concern that the novel β-coronavirus, SARS-CoV-2, could be transmitted to naïve North American bat populations through human contact, and once infected, bats could experience mortality and become a reservoir for the virus with the potential to re-infect people in the future. The goal of this assessment is to provide timely scientific information to guide State and Federal wildlife management agency response to this potential risk. The rapid emergence of SARS-CoV-2 in human populations created significant uncertainty in forecasting the risk of transmission to native bat populations. Along with decision makers from State and Federal agencies, we framed the management decision using principles of decision analysis, identified important objectives, and articulated potential mitigation actions. By framing the decision explicitly, we were able to provide information specifically useful for risk mitigation.

The World Organisation for Animal Health (OIE) Aquatic Animal Health Code defines a risk analysis as being composed of four parts: hazard identification, risk assessment, risk management, and risk communication (World Organisation for Animal Health, 2019, Chapter 2.1). The first step is the identification of a pathogen which may pose a hazard to wildlife. The second step, which is the aim of this report, provides decision makers with an objective and defensible method of assessing the risk associated with the pathogen. The third step is the implementation of risk management actions to mitigate the identified risk. Communication occurs throughout the process.

Uncertainty is the central challenge of risk management for decision makers—how to estimate the uncertainty and how to understand risk tolerance in choosing an action in the face of uncertainty. A quantification of risk combines the uncertainty in the range of outcomes and some measure of the potential harm under those outcomes. By framing the mitigation decisions with wildlife management agencies, we identified the outcomes that agencies wanted to avoid (the objectives articulated in the "Decision Framework" section). The task described in this report was to estimate the probability of several early steps in the causal chains that lead to those undesirable outcomes. Because of uncertainties about the distribution of the SARS-CoV-2 pathogen in the human population, the likelihood of transmission to bats, and the probability of infection given exposure, we combined expert elicitation and a model for the number of infected bats to estimate the current risk of transmission and the potential level of mitigation provided by the expanded use of PPE for individuals that conduct work with bats. Here, we considered risk as the combined probability of an event happening (that is, the transmission of SARS-CoV-2 from an infected human to a bat) and the magnitude of the undesired outcome (that is, persistence of the coronavirus within bat populations). The level of risk mitigated by a management intervention is determined by the reduction in likelihood of an undesired event and in the reduction of magnitude of the effect of the undesired event. Our aim was to provide decision makers with a risk assessment that could inform their risk management decisions in the near term, for activities that could affect bats over the next 6 months (April–November 2020).

Summary of Results

Our analysis finds a non-negligible risk of transmission of SARS-CoV-2 to bats from humans conducting research, survey, management, rehabilitation, and wildlife control activities. For example, our expert panel estimated that if a research scientist is shedding virus while handling bats under status quo protocols, 50 percent (15–84 percent) of those bats will be exposed to virus, and 17 percent (3–51 percent) will become infected. Although there were differences in exposure potential among the three transmission pathways (RSM, WR, and WC) and the three encounter types, without additional protective measures the probability of transmission resulting in infected bats cannot be ruled out. We found that the type of work being conducted changed the underlying risk; as expected, conducting work in proximity to bats (but in an unenclosed space) had a much lower risk of exposure than direct handling of bats.

We found that the use of PPE is expected to significantly reduce the exposure probabilities for all three modes of encounter with bats. The expert panel estimated that exposure risk from research scientists could be reduced by 94–96 percent (uncertainty, 86–99 percent) through proper use of appropriate N95 respirators and dedicated clothing and gloves.

Finally, we estimate that the median likelihood of bat-to-bat transmission is lower than the value for sustained transmission (that is, the median R_0 value is less than 1.0). However, there was significant uncertainty for this rate, and there remains a reasonable probability (approximately 33 percent) that sustained bat-to-bat transmission will be possible should SARS-CoV-2 be introduced into a wild free-ranging bat population. Further research to better understand bat-to-bat SARS-CoV-2 transmission is warranted.

Scope of Inference

There are some potential limitations to our assessment. We used the little brown bat as a surrogate species for all North American bats for this risk assessment. The little brown bat is one of the most widespread species of *Myotis*, a genus which is diverse and widespread in North America (O'Shea and Bogan, 2003). This species frequently inhabits buildings (Fenton and Barclay, 1980; Kunz and Reynolds, 2003) and is commonly captured for scientific field work (for example, Frick and others, 2010), which leads to a potential for virus transmission from humans to bats. We asked the expert panel to think specifically of little brown bats while they were responding to the elicitation. Our ability to extend the conclusions of this study to other North American species of

bats depends on the similarity of behavior, ecology, physiology, cellular biology, and genetics of those species to little brown bats.

The scope of inference for this analysis was limited to the active period for little brown bats, which we defined as the period from April 15 (when the bats leave hibernacula for maternal roost sites) through November 15 (when individuals return to hibernacula). This is when we expected the greatest contact rates with humans to occur. Because the active season for bat research, wildlife rehabilitation, and wildlife control activities was imminent, our assessment was designed to provide information to management agencies to update interim guidance to these groups. The expert panel and the modeling included herein focused on the active season. It is reasonable to think that the dynamics of exposure, infection, and subsequent transmission may be different during the hibernation season. Subsequent work may be needed to assess the risks for winter bat field work.

For PPE, we considered proper training, oversight, and use of dedicated clothing, gloves, and N95-type respirators. We expected use of PPE to have the largest effect on reducing bat exposure probability. In the elicitation, we did not make a distinction between vented and non-vented respirators, but from the discussion we assumed the experts were thinking about N95 respirators designed to filter exhaled particles. We did not specifically ask the expert panel about the use of alternative face coverings (like surgical masks), nor did we ask the experts to estimate the difference in efficacy of PPE among RSM, WR, and WC workers. In an open-ended question, some members of the expert panel did expect that proper and consistent use of appropriate N95 respirators might vary among groups. Note that other face coverings, including surgical masks, may be effective for reducing the transmission of SARS-CoV-2 because they have been found to be effective for human coronaviruses (Leung and others, 2020), but we do not know whether they will mitigate the transmission risk to the same level as expected for N95 respirators.

Key Assumptions

The inference in this report extends to regions with populations of little brown bats. The analysis contains an assumption that the number and modes of exposure reported by the 7 states, 3 agencies, and the WNS surveillance program represent the proportional encounter rates across the range of the little brown bat. Estimates of human exposure, shedding duration, and the basic reproduction number for SARS-CoV-2 in humans are all currently uncertain. We used estimates of cumulative incidence in humans from the emerging literature, assuming that the cumulative incidence over 7 months (April–November 2020) will be between 0.17 and 0.71 with 80-percent confidence. The forecasts of Moghadas and others (2020) that form the upper end of this interval assume no self-isolation of symptomatic individuals and an infectious period of 4.6 days, although their forecasts including self-isolation have little effect on reducing the epidemic size and peak timing. We thus assume that the current practices of stay-at-home, quarantine, and social distancing may reduce the duration of the epidemic but do not affect the cumulative incidence; given the current uncertainty in the ability to enforce or maintain such social distancing we believe this to be a reasonable baseline estimate to include in the risk assessment. Further, the reported cases do not include the asymptomatic individuals, and the estimated reporting rate (Bommer and Vollmer, 2020) is for actual cases attributed to COVID-19, so if the (adjusted) reported cases represent approximately 50 percent of the total infections (including mildly symptomatic and asymptomatic individuals; Nishiura and others, 2020; Li and others, 2020; World Health Organization, 2020; Ferguson and others, 2020; Mizumoto and others, 2020), then we believe this estimate to be reasonable for this risk assessment. We note that the asymptomatic portion of the population is a critical uncertainty, discussed in the section “Critical Uncertainties.” The experts were asked to assume that a worker who is infected (positive for SARS-CoV-2) is not showing symptoms. We used an estimated median shedding duration of 33 days—asymptomatic individuals would shed virus for the entire period and would still contribute to bat exposure; we assumed that symptomatic individuals would cease work within 1 day of symptom onset, and would not return to work until 14 days after symptoms resolved. This means that symptomatic individuals would expose bats for 3–4 days before stopping work because they are infectious before symptom onset (He and others 2020).

Experts were asked about their belief in the compliance of the different groups for proper use of PPE. We assume for this analysis that the average effect of PPE was identical across all individuals regardless of profession. Experts were uncertain whether the proportional change in the handling and proximity exposure probabilities for wildlife rehabilitators and wildlife control operators, owing to the same protocol guidance, would be different than for scientists.

Critical Uncertainties

Critical uncertainties are those uncertainties which, if resolved, would change the selection of a mitigation strategy. Because we framed this problem as a decision—identifying the management agencies, authorities, objectives, and potential interventions, and developing a model to link actions with the risk of bat infection—we can identify those uncertainties in the analysis that we would expect to change the risk assessment. At this stage, we have not conducted a value-of-information analysis (Runge and others, 2011) to verify that these uncertainties are critical to the decisions, in part because we have not yet evaluated the full causal pathways. Instead, we discuss below (1) uncertainties we evaluated, which strongly affected the probabilities of the early steps in the causal chains, and (2) uncertainties we have not yet evaluated, but which we judge could have a strong effect on the long-term outcomes and bear future examination.

Bat infection probability and sustained bat-to-bat transmission. These rates are related, and the probability a North American bat could become infected with SARS-CoV-2 was a significant uncertainty. Bats are known to maintain coronavirus infections, and experts expressed the opinion that North American bats were undertested for coronaviruses. New World bats from the Americas are known to host α-coronaviruses (Osborne and others, 2011; Dominguez and others, 2007), but β-coronaviruses may be relatively rare (Anthony and others, 2013; Góes and others, 2013). For the infection rate, σ_{ML}, there is some evidence that the probability of infection may be low (based on sequence matching of the ACE2 receptor; Damas and others, 2020; Luan and others, 2020) but possible; at this time we do not have results from experimental virus challenge trials in bats that would provide the most useful information. SARS-CoV-2 is a member of a group of viruses that is prone to host switching and recombination (Woo and others 2009), so transmission among species may be possible if it establishes in a population of a single species.

Species and regional differences. We also considered in our discussions *Eptesicus fuscus* (big brown bats) and *Tadarida brasiliensis* (Brazilian free-tailed bats), which also have widespread distributions but may have different human contact rates, infection probabilities, basic reproduction numbers, and transmission rates. The important questions to ask in extending this analysis to other species will be which parameters might differ and whether those differences might affect the baseline risk or the effect of proposed mitigation strategies. Species, communities, roost sites, availability, adherence to PPE guidelines, and the modes of interaction between bats and humans may all differ regionally.

The human probability of infection, shedding, and the amount of viral particles shed. The probability of transmission from humans to bats increases with both the duration of exposure and the quantity of viral particles shed. Shedding of viral particles changes over the course of infection and may peak even before symptoms manifest (He and others, 2020). It is unknown whether asymptomatic infected individuals shed virus in the same manner (duration and amount) as symptomatic individuals.

The asymptomatic frequency and shedding rate. A key uncertainty in estimating the exposure risk is the number of truly infected people that will encounter bats. We assumed for this analysis that individuals who are symptomatic are not conducting work with or near bats. Emerging evidence indicates that individuals may be infected with SARS-CoV-2 without showing symptoms. Estimates of the fraction of infections that are asymptomatic range from an average of 30.8 percent (Nishiura and others, 2020) to 86 percent (Li and others, 2020; also see World Health Organization, 2020; Ferguson and others, 2020; Mizumoto and others, 2020).

General public as a source of SARS-CoV-2. We did not estimate the potential transmission from the public at large to bats. Bats in the living spaces of houses may constitute a large fraction of the submissions for rabies testing, and it is estimated that many bats that are exposed to human spaces are released by the public rather than sent for testing. Further, people may not be aware of bats in their attics or barns and may expose bats to aerosols containing SARS-CoV-2. We assumed that contact from wildlife researchers, surveyors, managers, rehabilitators, and control operators would occur only when individuals were asymptomatic, but people recovering from infection in their homes may also expose bats roosting or trapped in homes.

Future Steps

From a rapid initial risk assessment associated with a subset of the parameters in the full influence diagram (fig. 1), we aim to provide information to decision makers that they can apply in their specific settings. Ultimately, how agencies use this decision framing and risk assessment may differ across agencies, taking into account their specific mandates. Different decision makers may tolerate varying amounts of risk (that is, agencies may have different acceptable levels of protection) and, thus, may choose to implement different sets of mitigation actions.

Future work may take several forms. First, we may improve upon the risk assessment presented here with updated parameter estimates from empirical data. There is ongoing research of human and bat systems that can update our parameter estimates (for example, challenge trials for the R_0 and σ parameters for bats, and the components of the p^{+}_{RSM} parameter in humans). Second, we considered probability of exposure and infection for the active field season only; different kinds of work, with potentially different exposure and infection risks, are conducted during the winter hibernation period. Guidelines developed from this risk analysis for wildlife scientists, rehabilitators, and control operators may differ for winter work. Third, we focused on a subset of State and Federal agencies. We may expand the scope of future assessments to include a larger number of State, Federal, and tribal agencies. Fourth, we focused only on the initial transmission stages (fig. 2) and did not evaluate the remaining steps in the causal diagram (fig. 1). Work on the remainder of the system diagram would include re-transmission to humans, domesticated animals, and other wildlife, and may reveal other management actions that could reduce the risk to the full set of objectives that are important to management agencies. In addition, there are more complex dynamics within the causal diagram that might be important to study, like the interplay between WNS and coronavirus shedding in bats (Davy and others, 2018). Fifth, we consider risks to bat populations from human exposure, but there are other human-animal interactions that may present risk to wildlife populations. A node was included in the influence diagram for feral and domestic cat infection because there is increasing evidence that felids may sustain infections (Shi and others, 2020). Given that feral and free-ranging cats already pose a significant risk to wildlife populations, including zoonotic disease (Medina and others, 2014), it may be important to expand the influence diagram and estimate the probabilities along this exposure route.

Summary

This report describes a risk assessment led by the U.S. Geological Survey, in cooperation with the U.S. Fish and Wildlife Service, to examine the possibility of reverse zoonotic transmission of SARS-CoV-2, the coronavirus that causes the human disease COVID-19, from humans to bats in North America. The study was undertaken to inform State, Federal, and tribal wildlife management agencies in the United States that manage some aspects of the interactions between humans and bats and are in the process of developing guidance.

The study was designed by first framing the decisions that concern State and Federal wildlife agencies, with a focus on the long-term outcomes the agencies desire and the near-term mitigation actions that are within their authority to implement. From these components, a causal diagram was developed to trace the linkages from the potential actions through intermediate steps to the desired outcomes. The subsequent risk analysis focused on the early steps of three transmission pathways, namely the exposure and infection of bats from research, survey, monitoring, and management activities; wildlife rehabilitation; and nuisance wildlife control operations. The assessment focused on the immediate field season, from April to November 2020, and used little brown bats as a case study and as a surrogate species for other North American bats.

From the causal diagram, a quantitative model was developed to forecast the number of infected bats using estimates of the number of bats handled through the three transmission pathways, the probability of exposure through various modes of encounter, the probability of infection conditional on exposure, and the probability that a worker is actively shedding the SARS-CoV-2 virus. The parameters in this model were estimated primarily through a formal process of expert judgment.

The expert panel estimated that, if a research scientist were shedding virus while handling bats under the protocols in use prior to the COVID-19 pandemic, 50 percent (15–84 percent) of those bats would be exposed to virus, and 17 percent (3–51 percent) would become infected. Although there were differences in exposure potential among the transmission pathways and encounter types, without additional protective measures, the probability of transmission resulting in infected bats cannot be ruled out. The expert panel expected that proper use of personal protective equipment would significantly reduce the exposure probabilities for all modes of encounter with bats. For example, the panel estimated that exposure risk from research scientists could be reduced by 94–96 percent (uncertainty, 86–99 percent) through proper use of appropriate personal protective equipment (such as N95 respirators and dedicated clothing and gloves). Regarding the possibility of sustained bat-to-bat transmission of SARS-CoV-2 in a wild population of little brown bats, the expert panel estimated a median basic reproduction number (R_0) of 0.45, but expressed considerable uncertainty, such that there was a 33-percent chance that R_0 could be greater than 1; these results indicate that sustained transmission within bat populations is a possibility, if SARS-CoV-2 is introduced.

This research was conducted at a time when there were few empirical studies of SARS-CoV-2 in North American bats, so there was considerable uncertainty in the results. As new information becomes available, the risk model can be updated with data concerning human infection rates, bat infection rates, and other parameters. Future work could look at the risks posed by field work after November 2020 (that is, during the hibernation season), as well as later steps in the causal diagram.

Appendix 1. Instructions for the Expert Panel

This appendix contains that exact documents that were provided to the experts during the expert elicitation process. The contents of this Appendix have not been edited to conform to USGS editorial standards.

Introduction to Expert Elicitation for an Expert Panel

Justification for an Expert Elicitation

Ideally, we would obtain parameter estimates from empirical data and associated mathematical models. Because these information are unavailable and time is of the essence for decision makers, we aim to use an expert panel to elicit parameter values with associated uncertainty, using techniques of expert judgment that utilize best available scientific information, account for uncertainty, and reduce bias (Morgan, 2014; Sutherland and Burgman, 2015).

Expert elicitation is a formal, structured process of obtaining expert judgment for specific questions. An expert is someone who possesses substantive information on a particular topic that is not widely known by others. We know that experts have knowledge, often privileged knowledge, that accrues as a result of their research and experience, even about processes for which data have not been collected. The question is how to extract that knowledge accurately and precisely. Expert judgment is a quantitative expression of an expert's belief based on knowledge and experience; it is an informed belief. Expert elicitation can provide improved information over single-expert inquiry when a diverse group of experts is asked to provide estimates, using a facilitated approach with discrete opportunities for information sharing, provision of estimates, and review of summarized information (Martin and others, 2012). Expert elicitation, when conducted with the same level of rigor as the collection and use of empirical data, can result in reliable predictions (for example, O'Hagan and others, 2006; Speirs-Bridge and others, 2010; Runge and others, 2011; Martin and others, 2012; Adams-Hosking and others, 2016).

An expert elicitation is governed by specific protocols to avoid inherent biases resulting from cognitive traps. These cognitive traps are shortcuts, or heuristics, that serve us well for simple decisions but result in biased estimates for more complex tasks (O'Hagan, 2019). These biases include

- Availability bias (experts will be influenced by evidence or events that are easily recalled),
- Anchoring bias (experts fail to consider possible values far from an initial estimate),
- Overconfidence (experts tend to underestimate their uncertainty, and make forecasts that are too narrow),
- Representativeness bias (a tendency to think of probabilities related to readily available examples), and
- Motivational bias (an innate desire to further our own interests).

When the number of experts is limited, we would additionally be concerned about small-sample bias.

There are additional biases that arise through the behavior of groups. To some extent, these can be collectively referred to as "groupthink," the tendency for groups to converge too quickly on consensus estimates or decisions and to ignore or forget divergent views that are held by members of the group. In this way, groups of experts can be collectively overconfident, or even biased.

So, the methodological challenge of expert judgment is to reliably extract the desired information from each member of a group of experts, without falling into the cognitive and behavioral biases that can undermine such an exercise. The best practices in an expert judgment approach have evolved by considering this challenge, testing approaches via experiments, and recommending a set of protocols for conducting an expert elicitation.

Steps in an Elicitation

We are using a protocol based on a modified Delphi method called the IDEA protocol (Hanea and others, 2017), with the four-point elicitation method (Speirs-Bridge and others, 2010). There are six steps in the process:

1. Select experts;
2. Calibrate experts (seed questions and sharing available information);
3. Elicitation of parameter values (4-point method);
4. Summary, review, and discussion (aimed at reducing linguistic uncertainty—relating to the instructions—and sharing insights, not to reach consensus);
5. Experts revise their initial values (if desired); and
6. Aggregate information across experts.

Steps 3–6 comprise a modified Delphi approach (described below).

Selection of Experts

Experts are individuals with specific subject-matter experience and knowledge. Experts should have relevant expertise which may come from formal training and be demonstrated by professional accomplishments such as peer-reviewed publications, familiarity with and knowledge of the system or related systems, willingness to participate fully and impartially in an

elicitation process, and good interpersonal and communication skills (Ayyub, 2001; Fazey and others, 2006).

Groups of experts have been found to perform as well (in terms of providing information close to the true empirically observed data) as more specific experts (for example, Burgman and others, 2011). The expert panel should be diverse—possessing knowledge of North American bats, zoonotic disease, and possible mitigation strategies; representing multiple institutions, specialization, and gender. The optimal number of experts for a structured elicitation is between 5 and 12, with decreasing marginal benefit after 12 experts (Hogarth, 1978; Hemming and others, 2018).

Training Questions

Before starting the elicitation concerning the questions of interest, we will provide the expert panel a chance to practice the elicitation methods. We will provide questions that are known (that is, we have identified values from the literature, but are unlikely to be known precisely by experts). We use these questions to ensure that the instructions are understood by experts, and to allow experts a chance to calibrate their estimates of uncertainty.

Three questions are listed below (see accompanying spreadsheet <BatEE Practice Questions v2.xlsx> [not included with this report]). For each question, we ask experts to provide four responses: an estimate that represents your view of the lowest reasonable value; an estimate of the highest reasonable value; an estimate that represents the best central value; and your confidence that the true value lies within the low and high values that you have provided. We have attached a spreadsheet in which you can enter these values; the spreadsheet automatically calculates a probability distribution that represents your uncertainty, as immediate feedback about whether your responses reflect your expert belief. This is a "closed book" exercise (we ask that you do not check this information in books or online). Please return your answers to us; we will use them to provide feedback to the group about your individual and collective accuracy and precision; as a means of allowing you to calibrate your thinking process prior to the elicitation for the questions of central importance.

The calibration questions are

1. What is the mean forearm length (in centimeters) of an adult little brown bat (*Myotis lucifugus*)?

2. What is the average number of subsequent white-nose syndrome infections resulting from a single infected little brown bat (that is, R_0)?

3. In a population that has already experienced decline due to WNS, out of 100 adult female little brown bats, how many would you expect to breed in a given year?

Elicitation of Parameters Using a Modified Delphi Approach

To generate empirical estimates of each parameter, we use a "4-point" elicitation method. This approach has been shown to reduce overconfidence in experts (Speirs-Bridge and others, 2010) and can generate a quantitative estimate from experts who may be uncomfortable providing estimates. We derive a median and credible interval for each parameter from the following four questions:

1. Realistically, what is the lowest reasonable value for the parameter?

2. Realistically, what is the highest reasonable value for the parameter?

3. Realistically, what is the most likely reasonable value (that is, your best estimate) for the parameter?

4. How confident are you that the true value is between the lowest and highest values you provided?

We then assume that the most likely value is the median value, and combine the upper and lower estimates and the reported confidence to generate a credible interval.

Experts provide their estimates anonymously, and summaries are provided that maintain anonymity, to avoid biases associated with group thinking and dominant personalities. Experts are encouraged to discuss the information during a facilitated discussion of the summarized data, after which experts have the opportunity to revise any of their estimates.

The modified Delphi sequence (independent-group-independent) is important to preserve the unique insights held by individuals while at the same time allowing the benefit of wisdom to be shared. By asking experts to perform the first estimate independently, their own personal views are captured. By allowing the expert to share and discuss their initial estimates, we can explore whether there is residual linguistic uncertainty that needs to be corrected and we can allow insights to be shared across experts. By allowing the final estimates to be made independently, we guard against dominant voices in the group and retain the diversity of insights among the experts.

Aggregation of Information Across Experts

Following the elicitation, we will aggregate the results to produce a single probability distribution that represents an estimate, with uncertainty, for each parameter. To do this, we will first transform the four-point elicitation results into a probability distribution for each expert. We will then average these probability distributions across experts, with equal weighting. (There are involved methods for weighting experts based on sets of calibration questions, but we are both skeptical of these methods and limited on time).

Questions for the Expert Panel

For each of the questions that ask for a quantitative response, we are asking you to provide a low estimate, a high estimate, a central estimate, and a degree of confidence that the true value is between your low and high estimates. Please see the document that provides instructions on expert elicitation that was sent by Evan Grant on April 9 [see "Introduction to Expert Elicitation for an Expert Panel"]. Please record your responses in the accompanying spreadsheet, which also provides graphical feedback.

In all the questions below, unless otherwise noted, we are thinking specifically about little brown bats (*Myotis lucifugus*) throughout their range in North America, with a focus on the time period between now and the initiation of hibernation in the autumn of 2020.

Questions 1–7 all involve estimation of an exposure probability in the absence of any new restrictions, regulations, or protocols, that is, under the status quo conditions for contact with bats that existed before the arrival of SARS-CoV-2 in North America. In the past, concern about biological agents has been primarily focused on rabies virus and the fungus *P. destructans*; typical protocols involve decontamination of clothing and footwear between sites, wearing nitrile gloves (with disposal or decontamination between bats), but use of face masks or respirators has not been typical.

Note that we are separating the processes of exposure and infection. By **exposure probability**, we mean the likelihood that a particular interaction between an average bat and a biologist who is actively shedding SARS-CoV-2 virus will result in exposure of the bat to a sufficient viral dose to cause infection. By **infection probability**, we mean the probability that the virus replicates in the host (bat) tissue, conditional on that bat having been exposed to a sufficient viral dose. That is, the exposure process is about whether enough virus was transferred to make an infection possible; it is a property of the interaction between the biologist and that bat. The infection process is about the molecular, cellular, immunological, and physiological conditions that allow replication in the bat; it is a property of the interaction of the bat and the pathogen. Questions 1–7 only ask if the bat will be exposed to a sufficient viral dose; Question 8 asks about the probability of developing an infection, conditional on exposure.

Questions 1–7 differ from each other in two respects: the exposure pathway (the types of work being conducted), and the degree of interaction. We consider three exposure pathways: through activities related to research, survey, monitoring, and management (RSM); through wildlife rehabilitation (WR); and through wildlife control operations (WC). We consider three degrees of interaction: handling; proximity in an enclosed spaced without handling; and proximity in an unenclosed space without handling.

1. Consider a wildlife biologist engaged in research, survey, monitoring, or management (RSM) who is actively shedding SARS-CoV-2 virus (CoV+), performing their routine activities in the absence of any new restrictions, regulations, or protocols. If that biologist **directly handles** 100 average little brown bats, how many of those bats do you estimate will be exposed to a sufficient viral dose of SARS-CoV-2 that they could become infected? (This relates to the parameter β_H^{RSM} in equation 1).

2. Same setting as question 1, a CoV+ biologist conducting RSM under status quo protocols. If that biologist is **in an enclosed space and within 6 feet** of 100 average little brown bats (but does not handle them), how many of those bats will be exposed to a sufficient viral dose that they could become infected? (This relates to the parameter β_E^{RSM} in equation 1).

3. Same setting as question 1. If the RSM biologist is ***not* in an enclosed space but is within a 6-foot proximity** of 100 little brown bats (and does not handle them), how many of those bats will be exposed to a sufficient viral dose that they could become infected? (This relates to the parameter β_P^{RSM} in equation 1).

4. Now consider a wildlife rehabilitator (WR) who is actively shedding SARS-CoV-2 virus (CoV+), performing their routine activities in the absence of any new restrictions, regulations, or protocols. If that rehabilitator **directly handles** 100 average little brown bats, how many of those bats do you estimate will be exposed to a sufficient viral dose of SARS-CoV-2 that they could become infected? (This relates to the parameter β_H^{WR} in equation 2).

5. Same setting as question 4, a CoV+ wildlife rehabilitator (WR) conducting their work under status quo protocols. If that rehabilitator **is within a 6-foot proximity** (whether enclosed or unenclosed) of 100 average little brown bats but does not handle them, how many of those bats will be exposed to a sufficient viral dose that they could become infected? (This relates to the parameter β_P^{WR} in equation 2).

6. Now consider a wildlife control operator (WC) who is actively shedding SARS-CoV-2 virus (CoV+), **performing their routine activities that involve handling bats**, in the absence of any new restrictions, regulations, or protocols. For example, a typical activity might involve capturing bats in a home or trapping and transporting bats from an attic. If that WC operator directly handles 100 average little brown bats, how many of those bats do you estimate will be exposed to a sufficient viral dose of SARS-CoV-2 that they could become infected? (This relates to the parameter β_H^{WC} in equation 3).

7. Same setting as question 6, a CoV+ wildlife control operator (WC) conducting their routine work under status quo protocols, but **without handling the bats**. For example, a typical activity might involve working in an attic to set up an exclusion device, or trapping bats without handling

them. If that WC operator is within a 6-foot proximity (whether enclosed or unenclosed) of 100 average little brown bats but does not handle them, how many of those bats will be exposed to a sufficient viral dose that they could become infected? (This relates to the parameter β_P^{WC} in equation 3).

The next question focuses on the probability of infection, conditional on exposure. (This relates to the parameter σ_{ML} in equations 1, 2, and 3.)

8. What is the probability that a little brown bat exposed to a sufficient viral dose of SARS-CoV-2 would actually become infected by the virus (that is, sustained viral replication would occur in their tissue)?

The next three questions focus on the efficacy of guidance and protocols to reduce the exposure rate. In all of these questions, the new guidance and protocols consist of: restriction of fieldwork to people without symptoms and without contact with someone who had symptoms of COVID-19 in the last 14 days; proper training and compliance protocols for the use of PPE; proper use of Tyvek or other dedicated clothing; proper use of an N95 respirator; and proper use of gloves for handling bats. In these questions, please assume that the biologists have proper training, have access to PPE, and are using it appropriately.

9. Consider your response to question 1, regarding exposure through handling by RSM scientists. By what proportion should this exposure probability be multiplied if the new guidance and protocols are put into place? (Note that a proportion of 1 means there would be no change in exposure probability; a proportion of less than 1 would indicate a reduction in exposure probability; and a proportion of greater than 1 would indicate an increase in exposure probability as a result of such guidance.)

10. Consider your response to question 2, regarding exposure through proximity in an enclosed space by RSM scientists. By what proportion should this exposure probability be multiplied if the new guidance and protocols are put into place?

11. Consider your response to question 3, regarding exposure through proximity in an unenclosed space by RSM scientists. By what proportion should this exposure probability be multiplied if the new guidance and protocols are put into place?

12. **Open-ended response**. Are there reasons to believe that the proportional change in the handling and proximity exposure probabilities for wildlife rehabilitators (WR) and wildlife control operators (WC), owing to the same protocol guidance, would be different than for scientists involved in research, survey, and management (RSM)? Explain.

The last question addresses the risk of sustained bat-to-bat transmission of SARS-CoV-2.

13. What is R_0 for SARS-CoV-2 in little brown bats during the active season? That is, for each infected little brown bat, how many other little brown bats would become infected with the virus? Note that R_0 can be less than 1, in which case you can think of it as the probability that an infected bat will infect one other bat, or it can be greater than 1, in which case each infected bat infects more than one other bat. Note that the spreadsheet [not included in this report] calculates from your responses the probability that R_0 is greater than 1.

We are grateful for your time and expertise. Thank you for your thoughtful participation in this elicitation.

Clarification Provided Between Rounds of Elicitation

During the discussion with the experts between Rounds 1 and 2 of the elicitation, the experts raised some questions about the typical activities of RSM, WR, and WC workers when encountering bats. The following clarifications were provided before the second round of elicitation was completed.

Because research on bats typically involves more than one scientist, we consider the number encountered by each member of a research team; the β parameters in equation 1 describe the exposure probability per scientist while conducting each of the activities. The description of typical handling procedures for researchers working with bats includes: 1–2 minutes of contact per bat, holding a bat within 12 inches of the face, taking morphometrics, and blowing on a bat to aid in determining reproductive condition or to discourage biting. Some research and management activities may involve longer holding periods for collection of metabolic measurements, attachment of radiotransmitters and other sampling, but these interactions are less common. The definition of enclosed space includes caves and mines with various sizes and morphologies that may result in variation in airflow among sites. We assumed that activity in enclosed space may be greater than 1 hour, and bats in these spaces may be a mixture of stationary (roosting) and in flight. Typical activities near bats but in an unenclosed space include a management agency conducting emergence counts outside a cave or mine entrance or under a bridge.

Typical activities of wildlife rehabilitators were assumed to include repeated contact with a small number of bats, involving hand feeding (especially for little brown bats), medical management of injuries, with a contact duration of weeks to months. We assumed that most rehabilitators typically dedicate an enclosed room for rehabilitation activities, with facilities that may range from a shed or garage to a purpose-built structure.

The definition of enclosed space includes attics of various sizes and dimensions that may result in variation in airflow among sites. Wildlife control operators typically do not enter enclosed spaces during the summer season, so as not to disturb bats who may be rearing pups. For bats within a home's living space, a wildlife control operator may catch a bat for release. We assumed that activity in enclosed space may be greater than 1 hour, and bats in these spaces may be a mixture of stationary (roosting) and in flight. Typical activities near bats but in an unenclosed space include a wildlife control operator working to exclude bats from a home (that is, installing an excluder device near soffits or eaves after young bats are flying and not likely to be trapped inside when their mothers go out to forage).

Appendix 2. Expert Elicitation Results

Results of responses to Questions 1–13 are shown in illustrations.

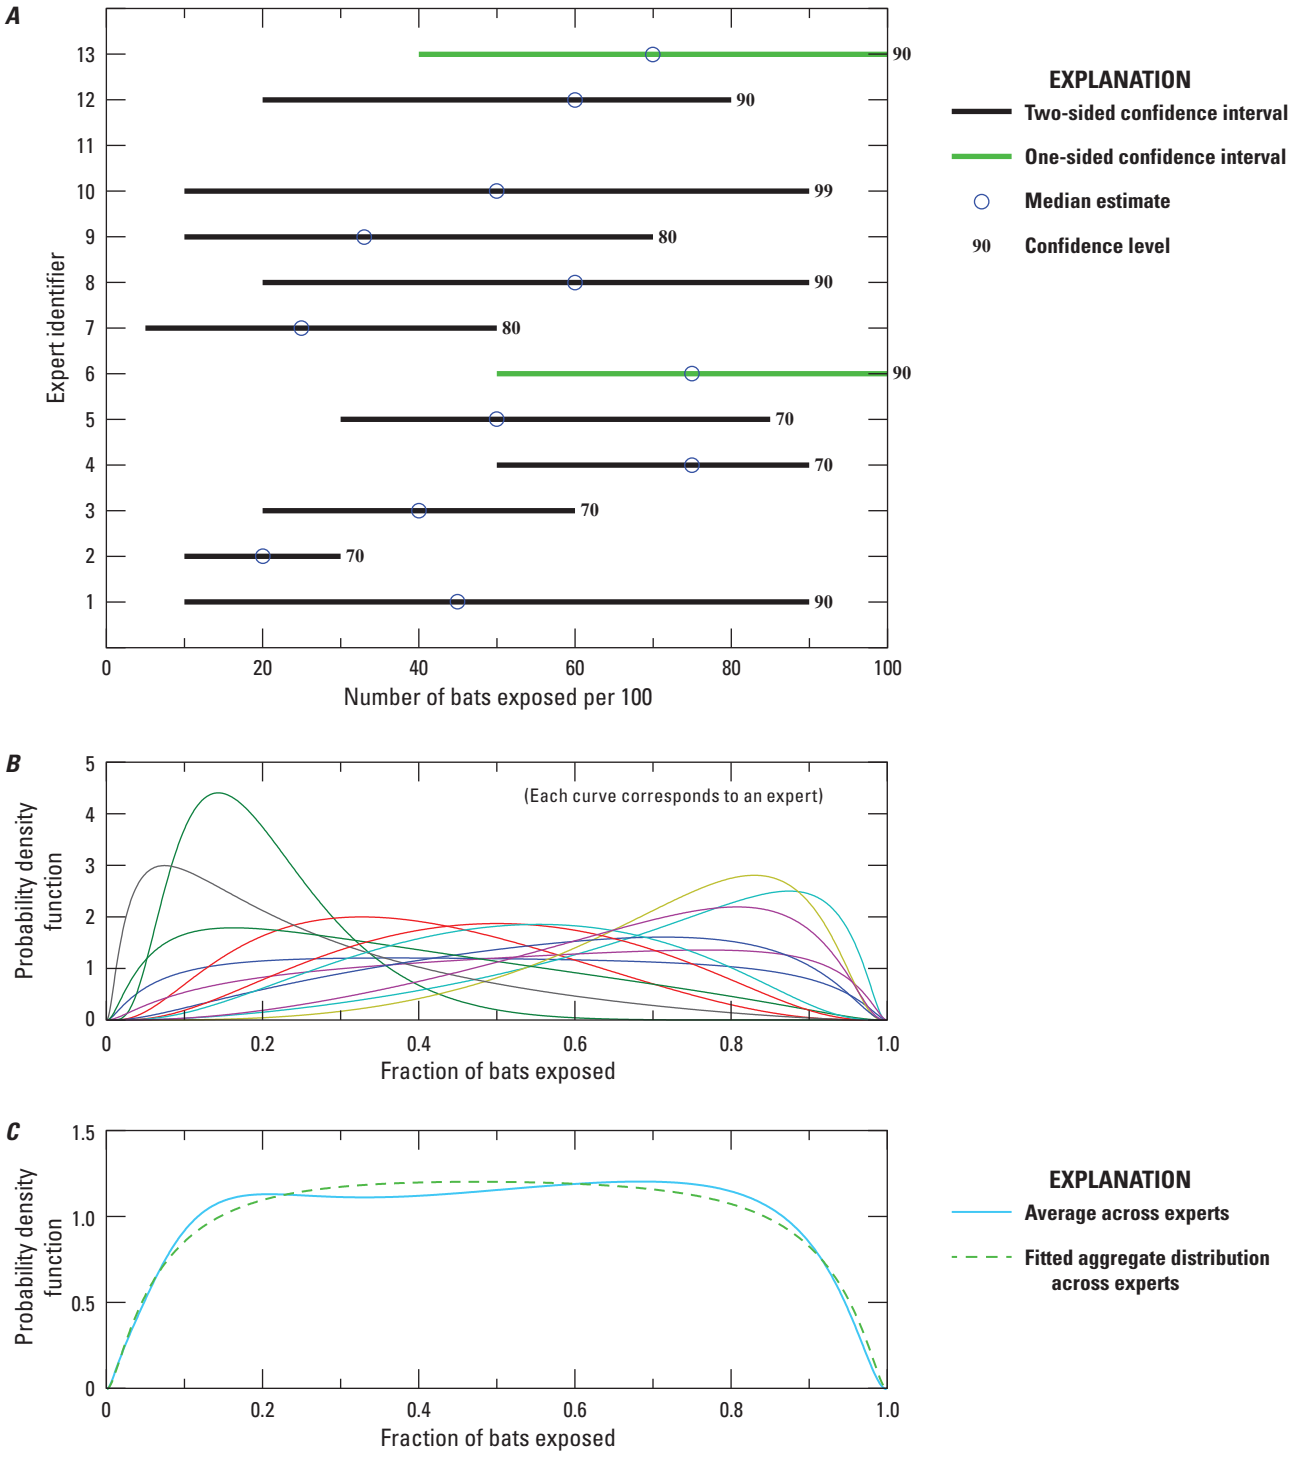

Figure 2.1. Expert panel responses to Question 1—number of bats exposed to virus by a SARS-CoV-2-positive scientist handling bats. *A,* Four-point-elicitation responses from the individual experts, *B,* fitted probability distributions for individual experts, and *C,* average and fitted distributions across experts. The aggregate distribution has a median of 49.7 bats and an 80-percent confidence interval of (15.3, 84.3).

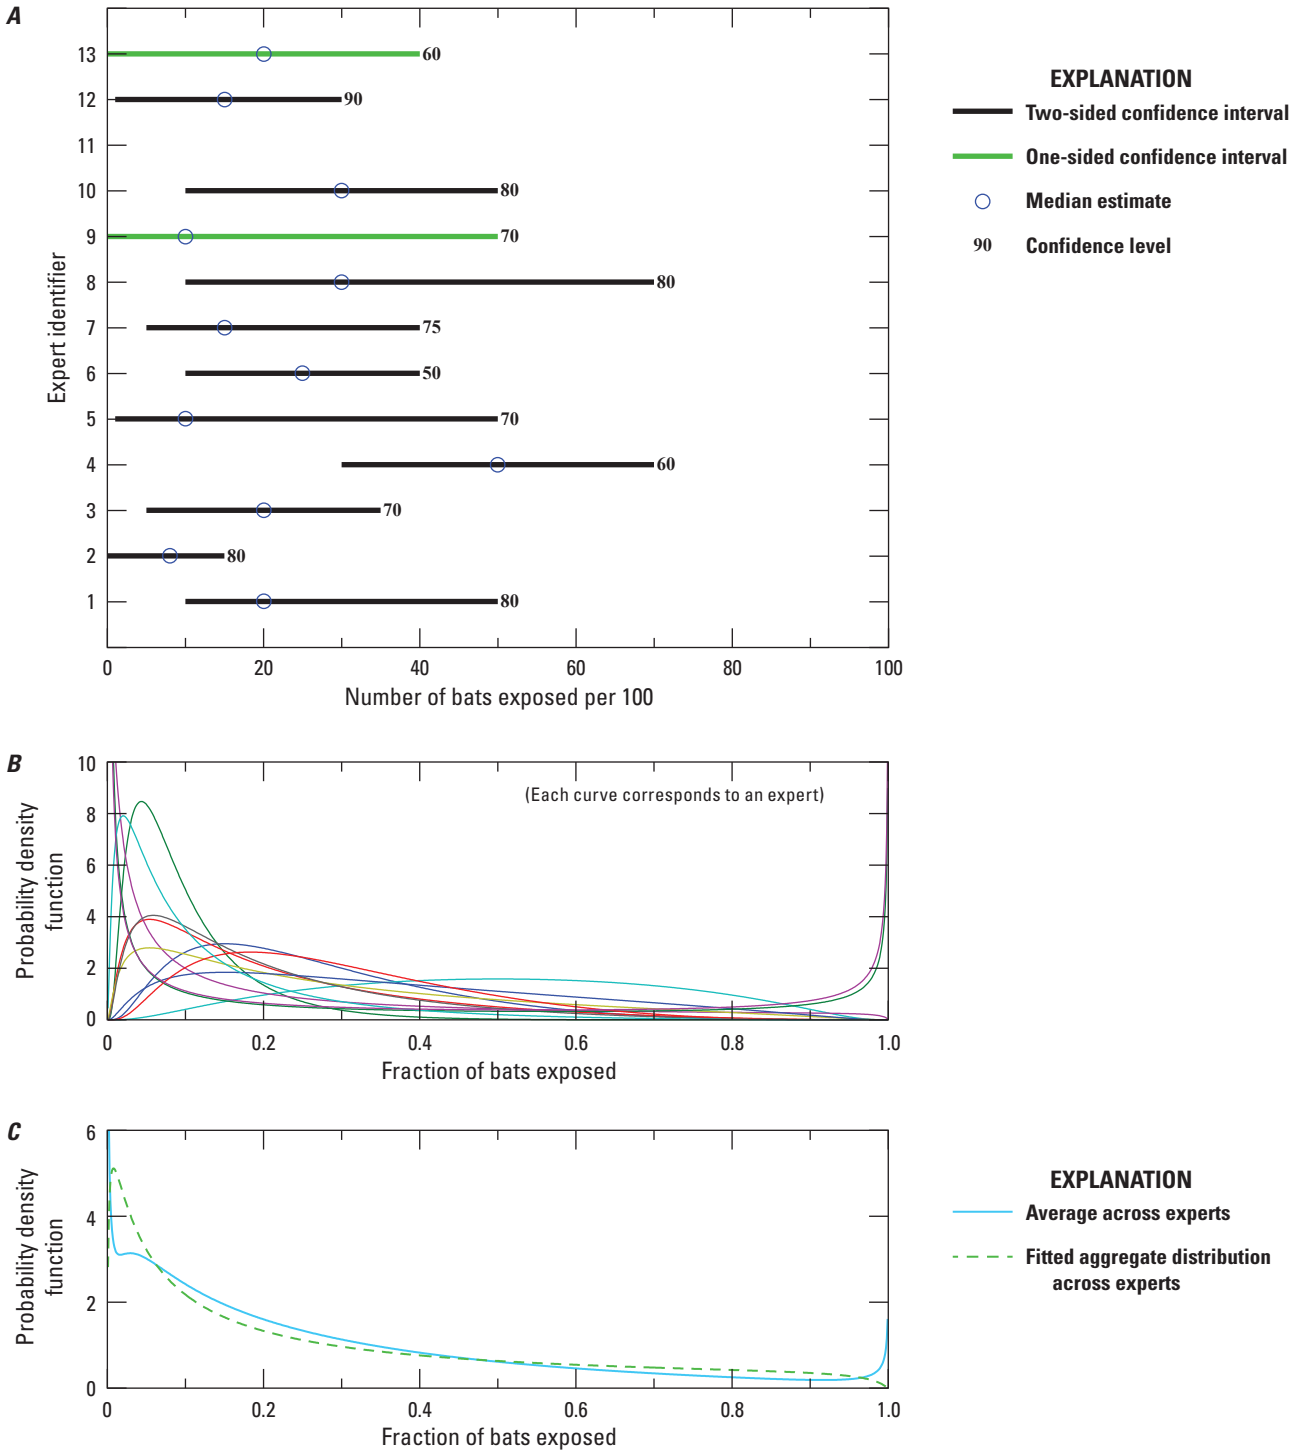

Figure 2.2. Expert panel responses to Question 2—number of bats exposed to virus by a SARS-CoV-2-positive scientist in an enclosed space within 6 feet of bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 19.4 bats and an 80-percent confidence interval of (2.2, 72.4).

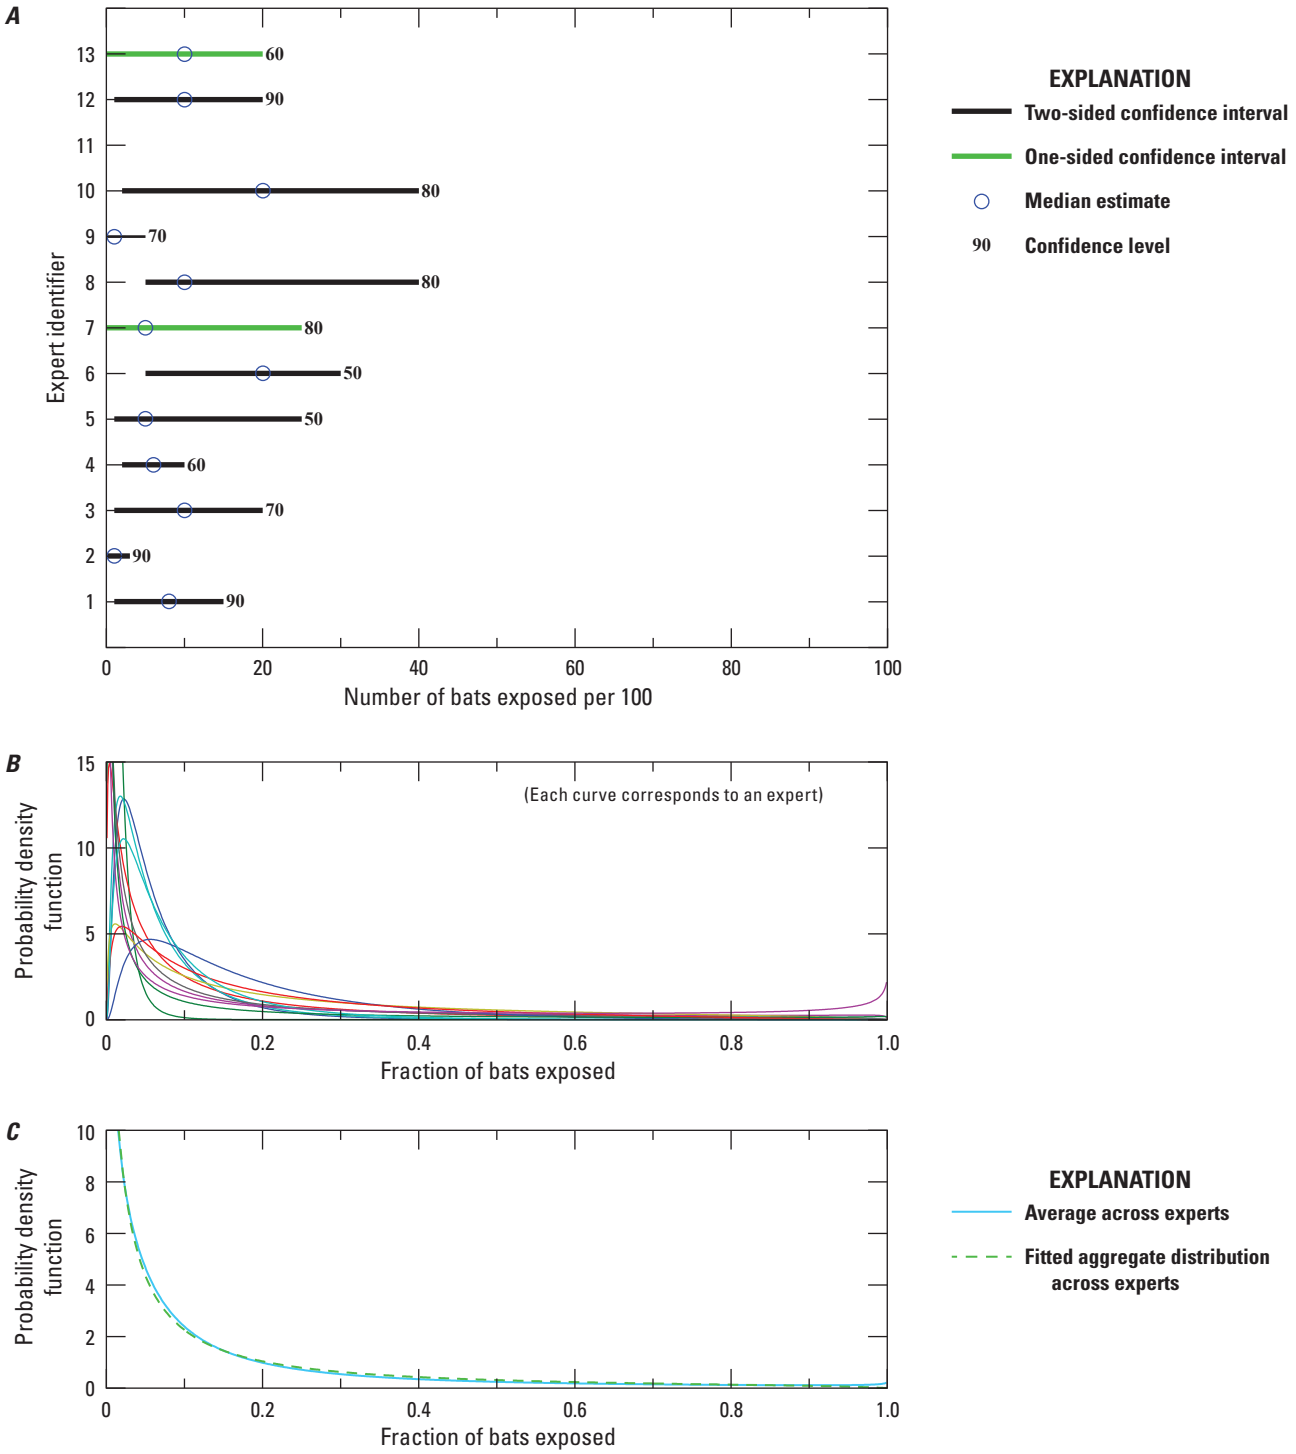

Figure 2.3. Expert panel responses to Question 3—number of bats exposed to virus by a SARS-CoV-2-positive scientist in an unenclosed space within 6 feet of bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 6.4 bats and an 80-percent confidence interval of (0.6, 43.8).

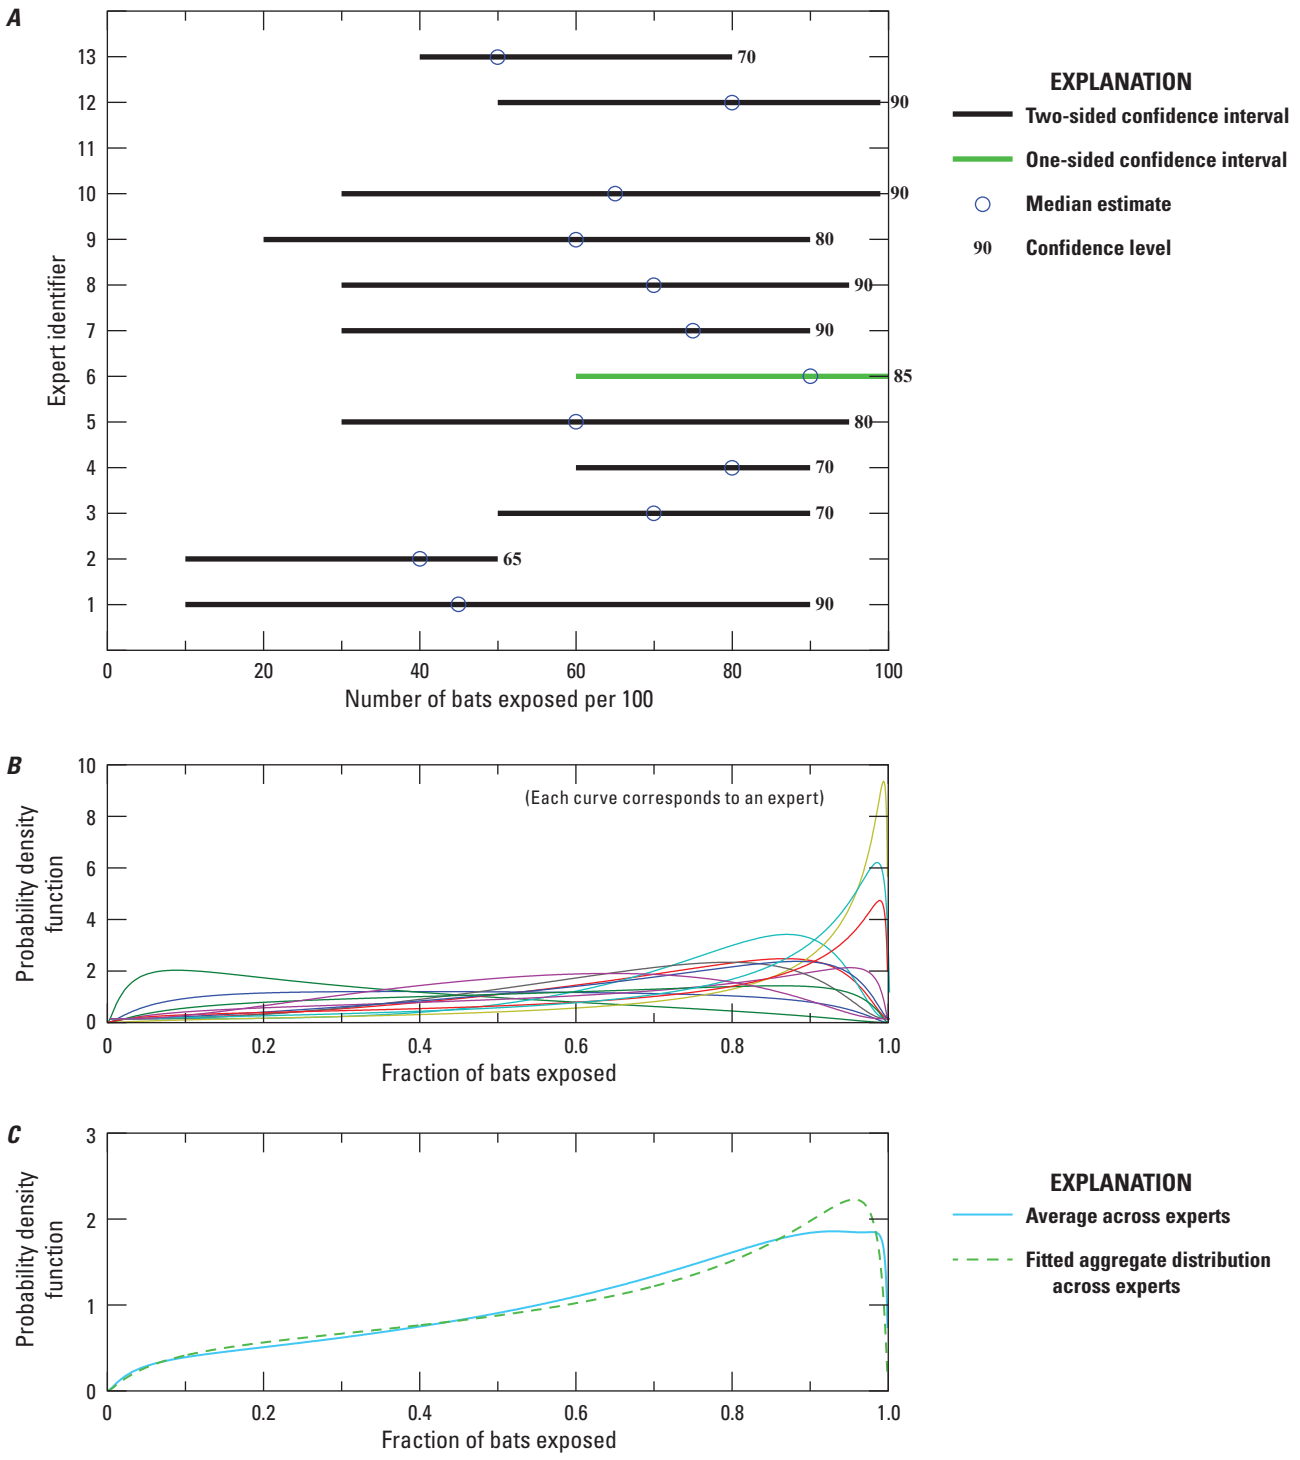

Figure 2.4. Expert panel responses to Question 4—number of bats exposed to virus by a SARS-CoV-2-positive wildlife rehabilitator handling bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 70.4 bats and an 80-percent confidence interval of (24.4, 94.6).

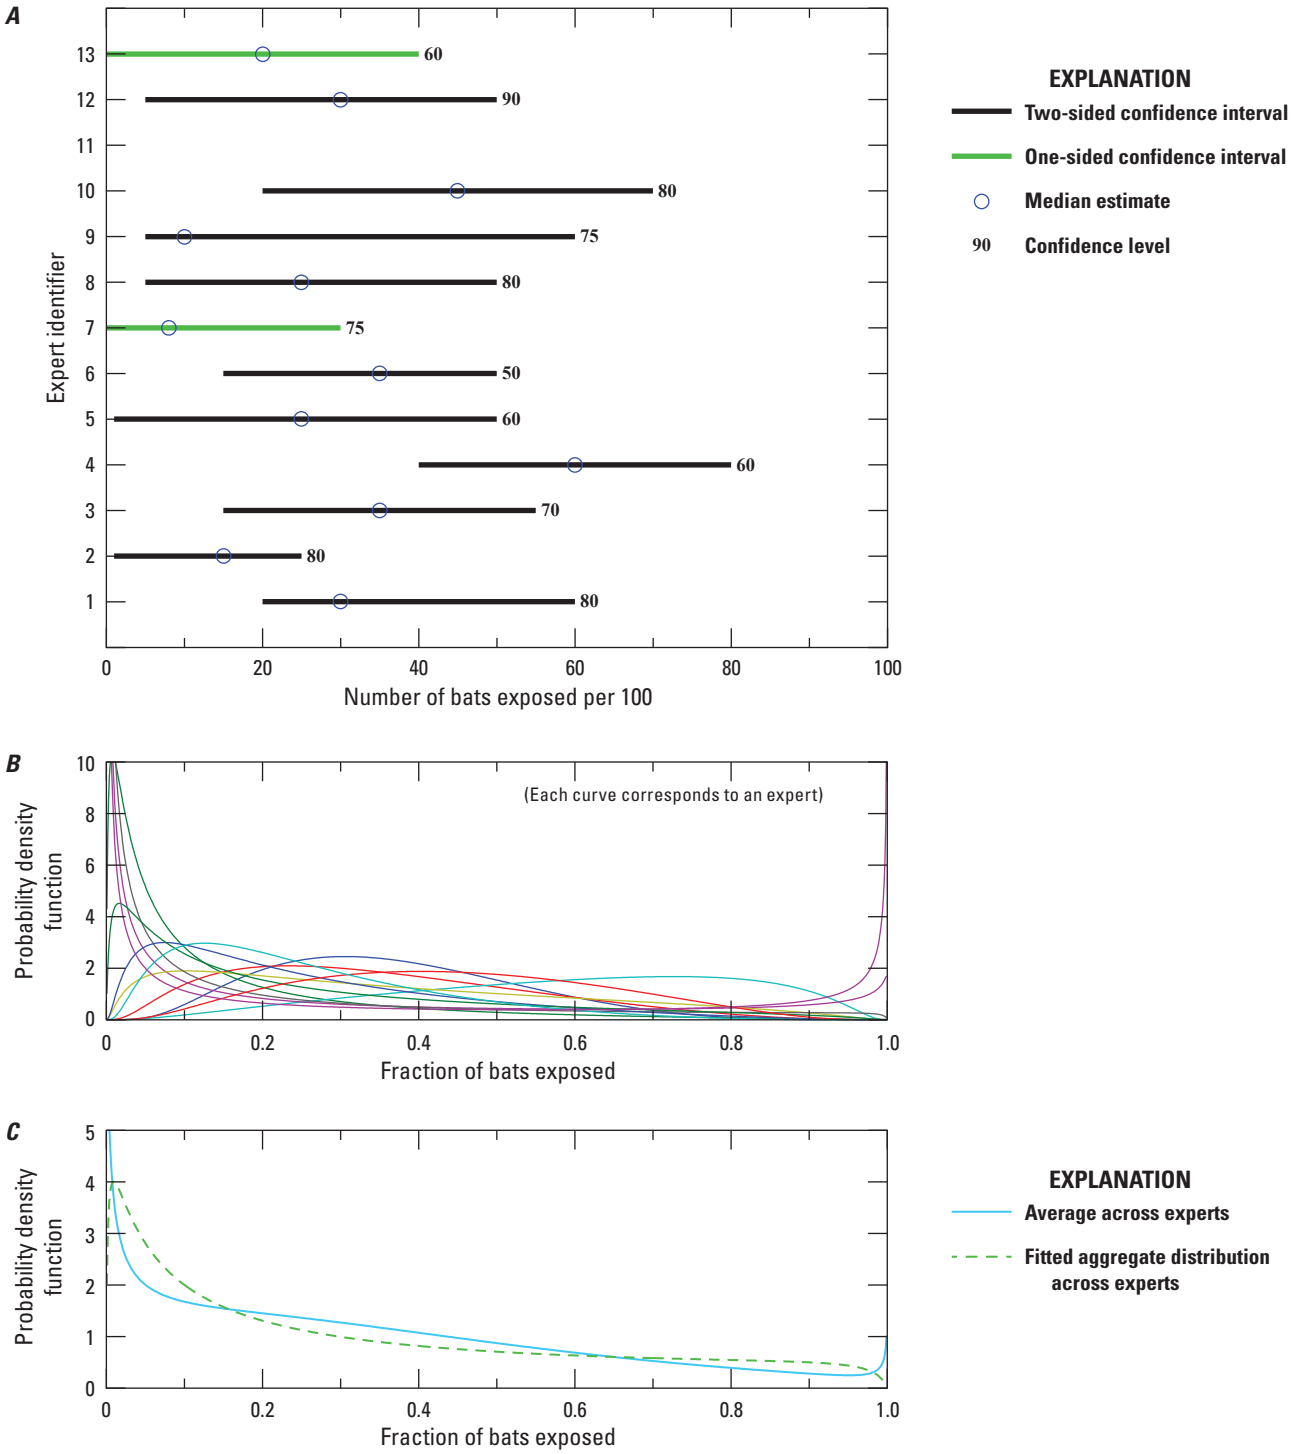

Figure 2.5. Expert panel responses to Question 5—number of bats exposed to virus by a SARS-CoV-2-positive wildlife rehabilitator within 6 feet of bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 24.3 bats and an 80-percent confidence interval of (2.8, 78.4).

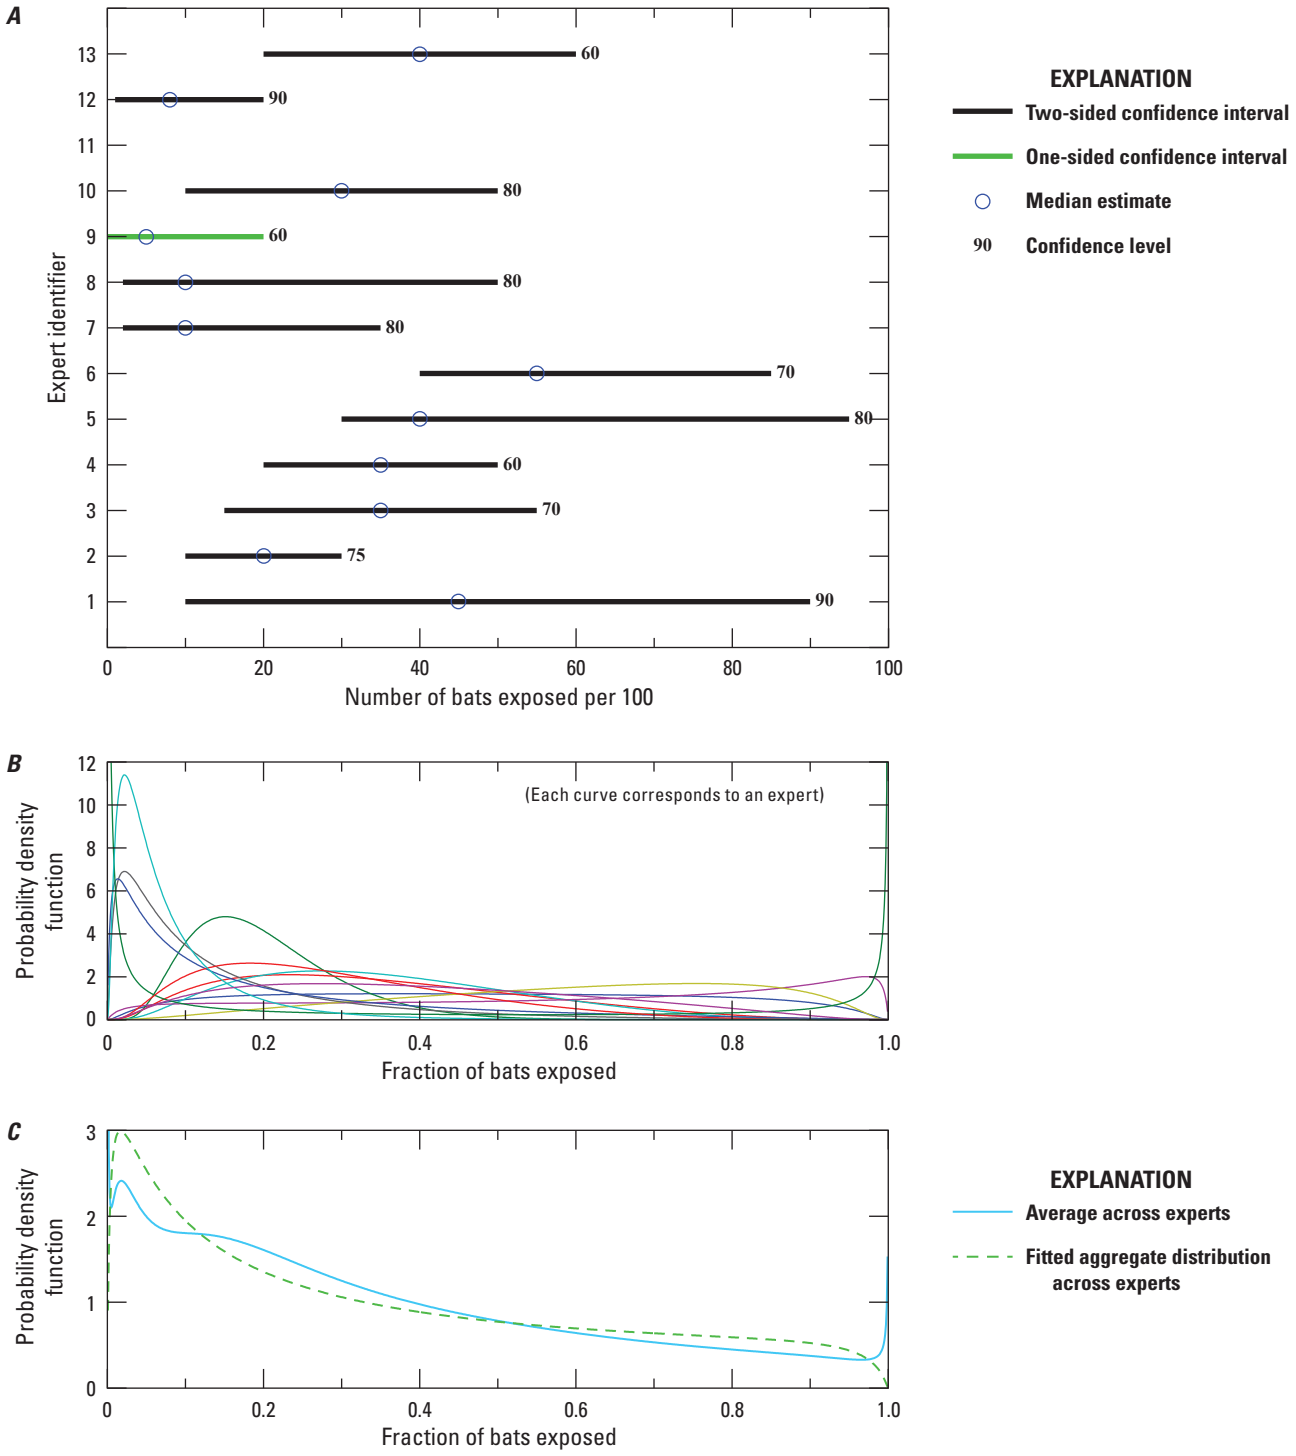

Figure 2.6. Expert panel responses to Question 6—number of bats exposed to virus by a SARS-CoV-2-positive wildlife control operator handling bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 27.7 bats and an 80-percent confidence interval of (3.7, 79.2).

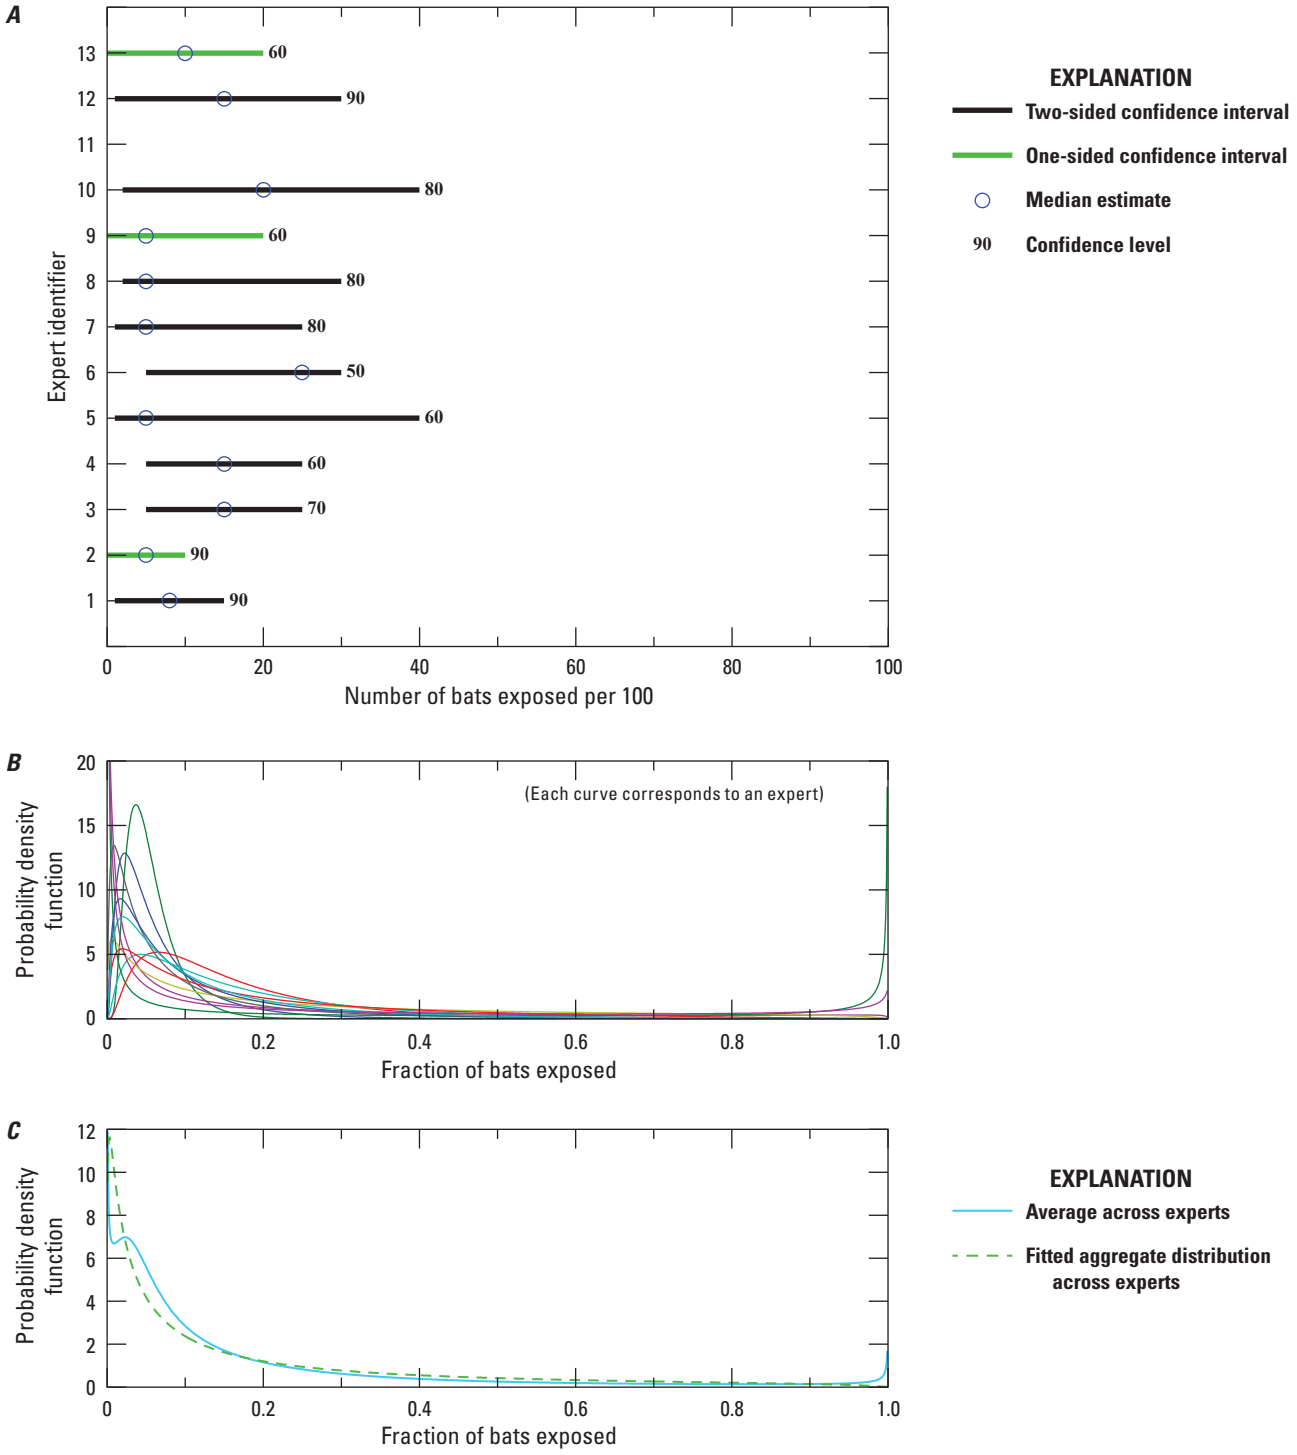

Figure 2.7. Expert panel responses to Question 7—number of bats exposed to virus by a SARS-CoV-2-positive wildlife control operator within 6 feet of bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 9.6 bats and an 80-percent confidence interval of (1.0, 53.9).

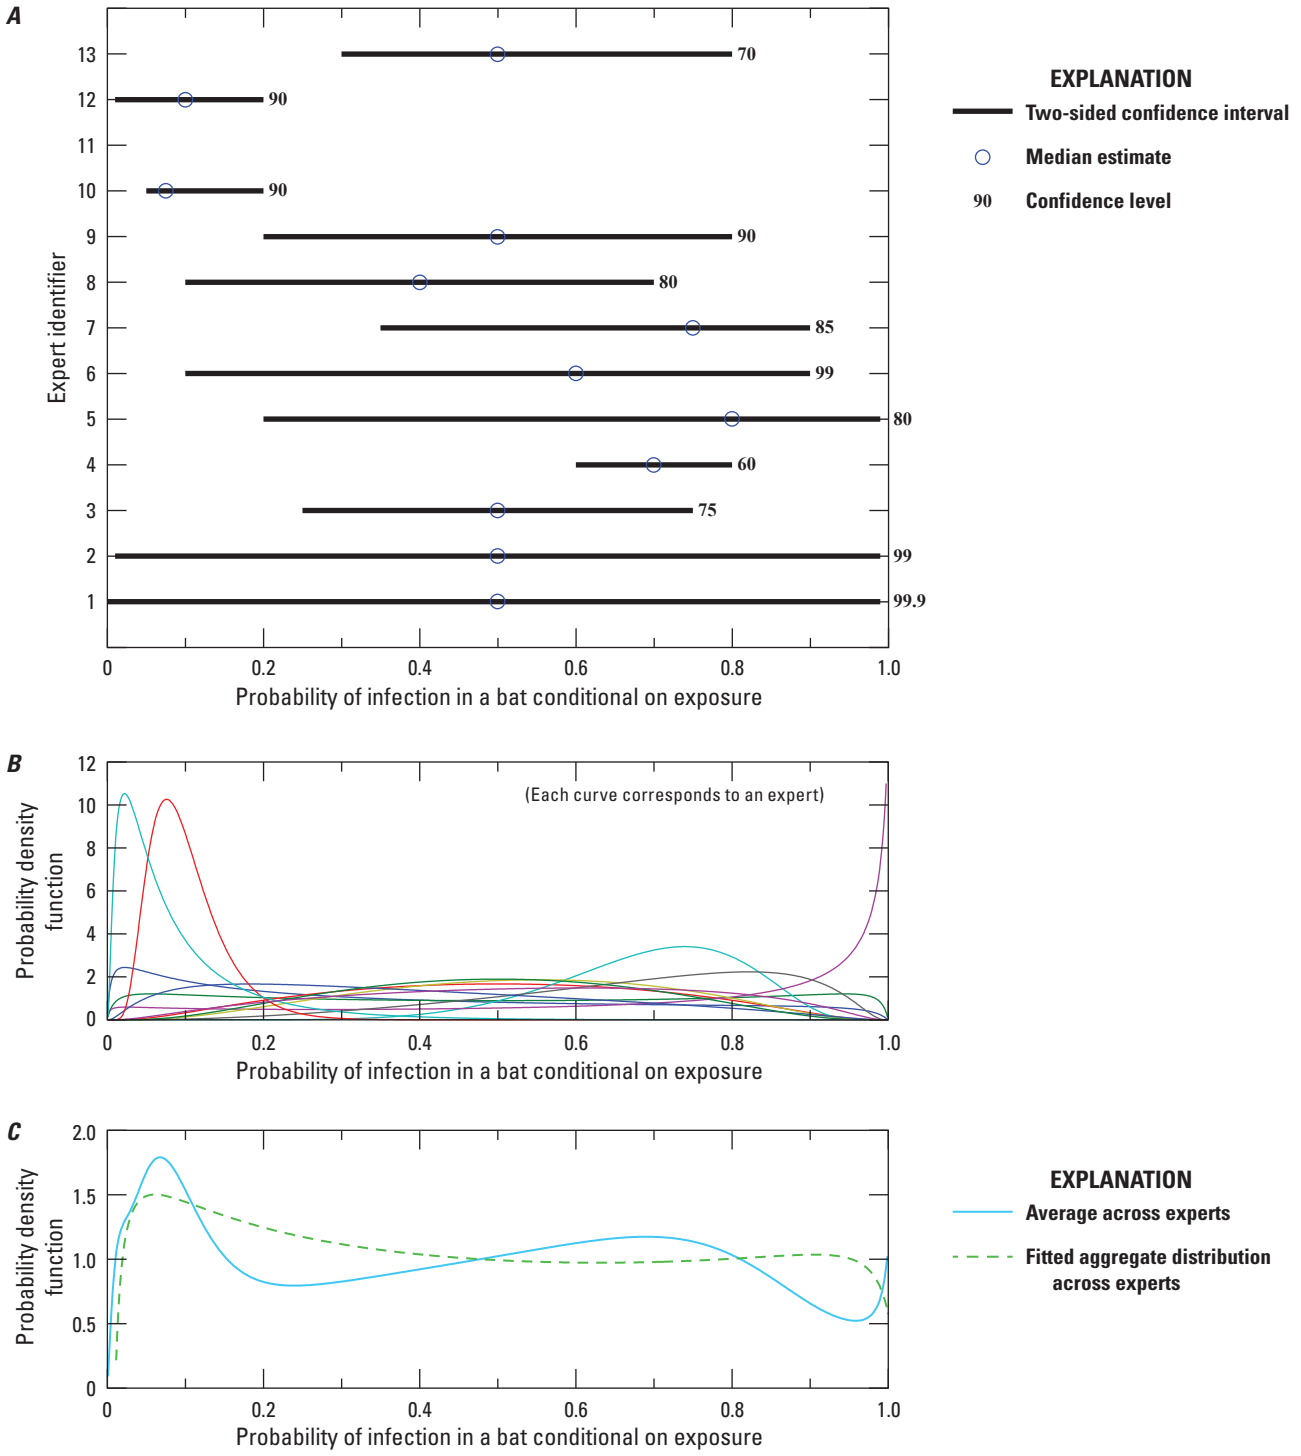

Figure 2.8. Expert panel responses to Question 8—probability of infection in a bat conditional on exposure. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 0.44 and an 80-percent confidence interval of (0.08, 0.88).

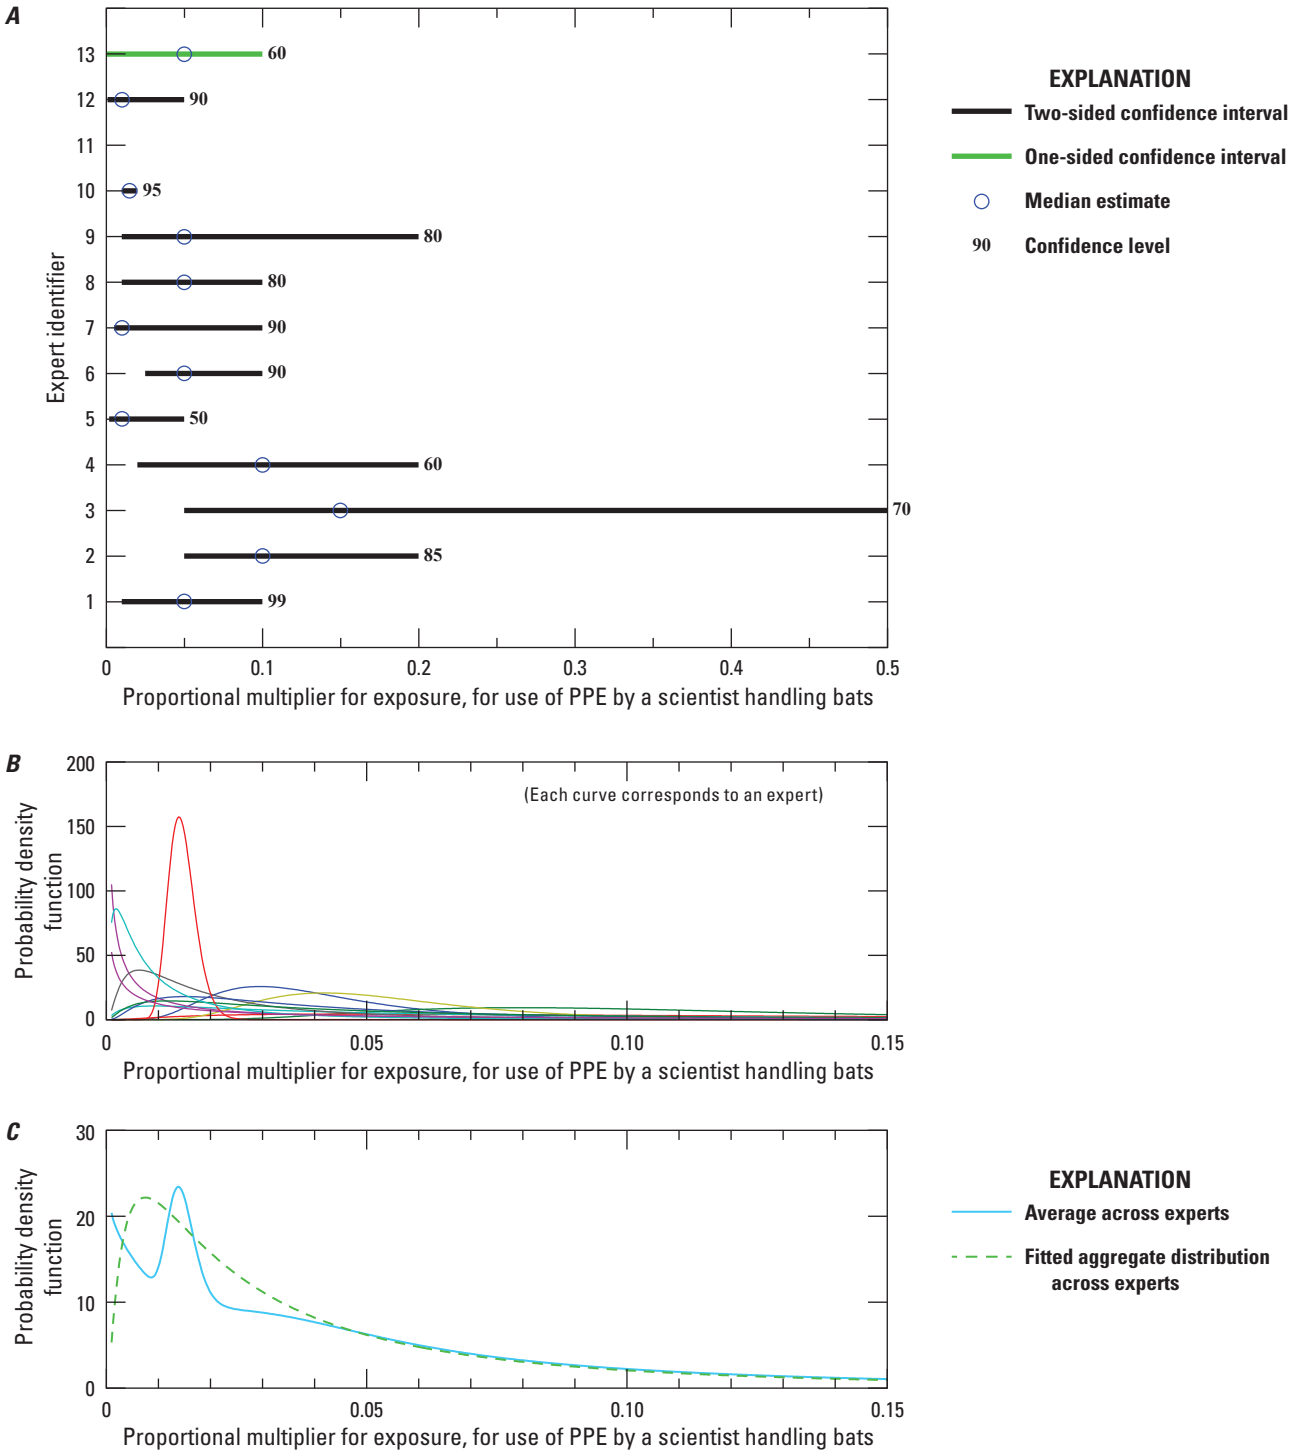

Figure 2.9. Expert panel responses to Question 9—multiplier for exposure, when using personal protective equipment, for a research scientist handling bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 0.031 and an 80-percent confidence interval of (0.007, 0.141). PPE, personal protective equipment.

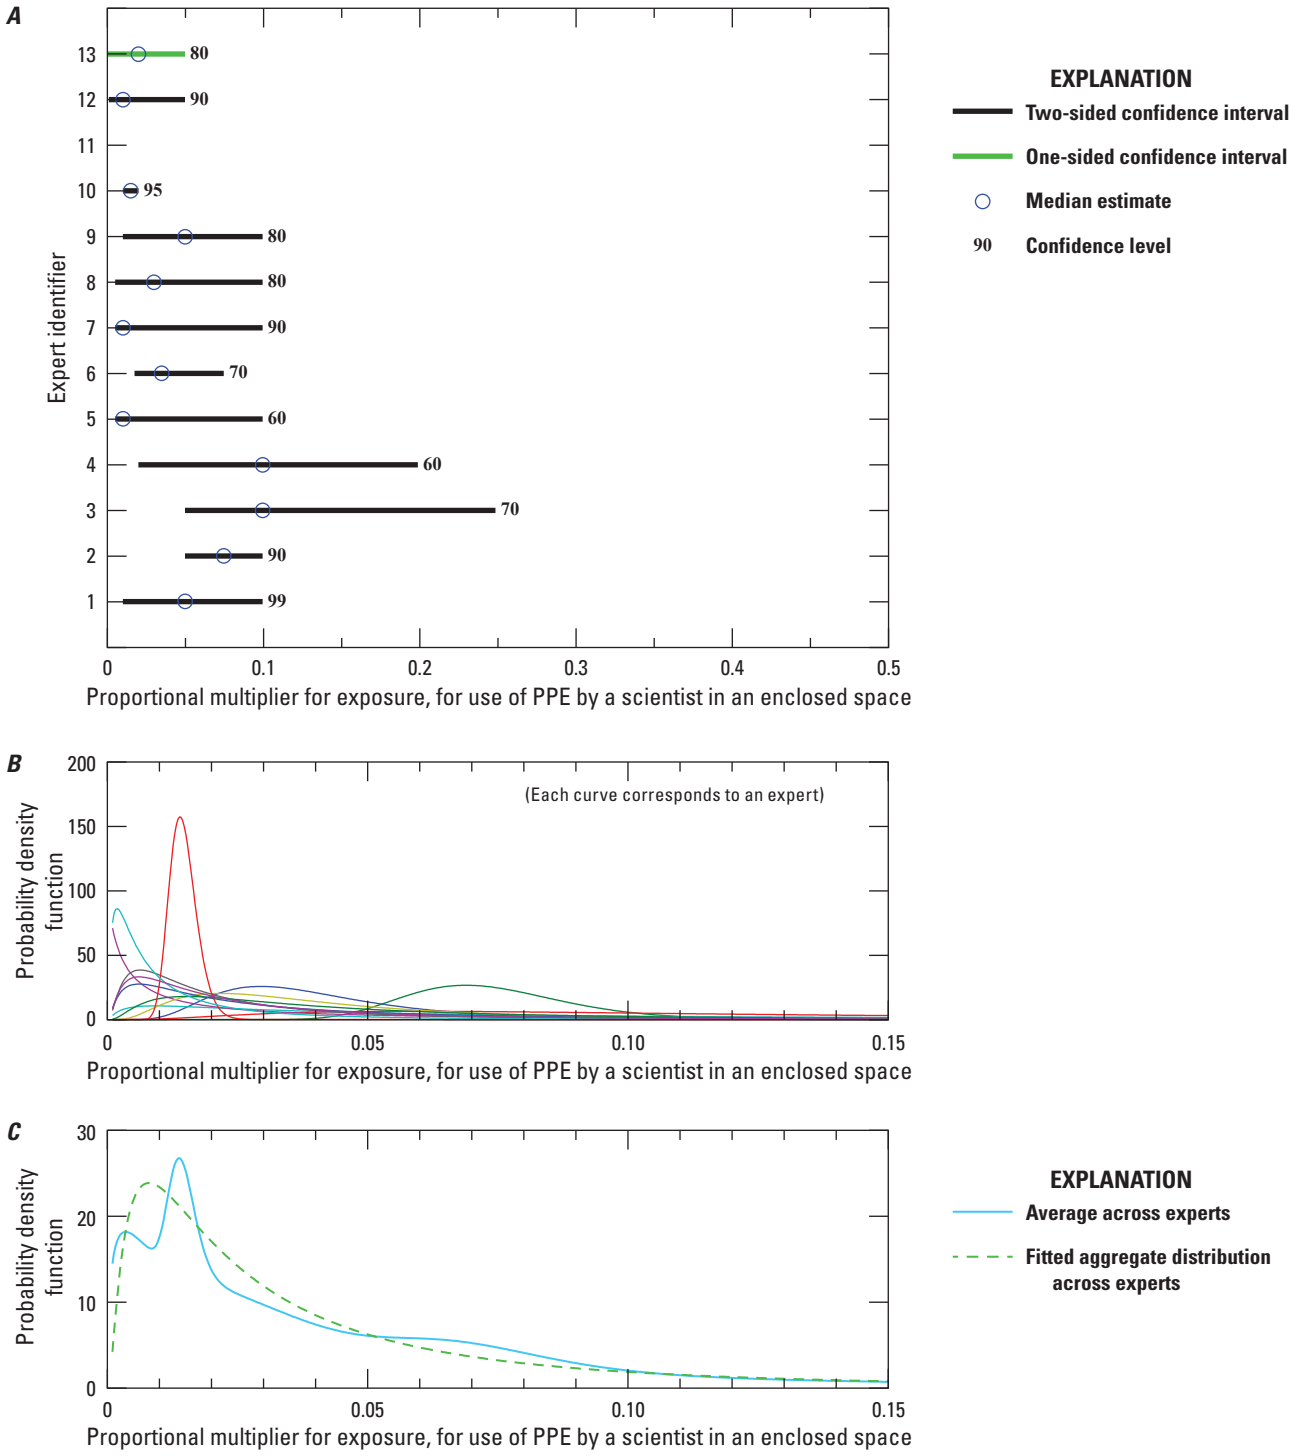

Figure 2.10. Expert panel responses to Question 10—multiplier for exposure, when using personal protective equipment, for a research scientist in an enclosed space within 6 feet of bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 0.028 and an 80-percent confidence interval of (0.007, 0.117). PPE, personal protective equipment.

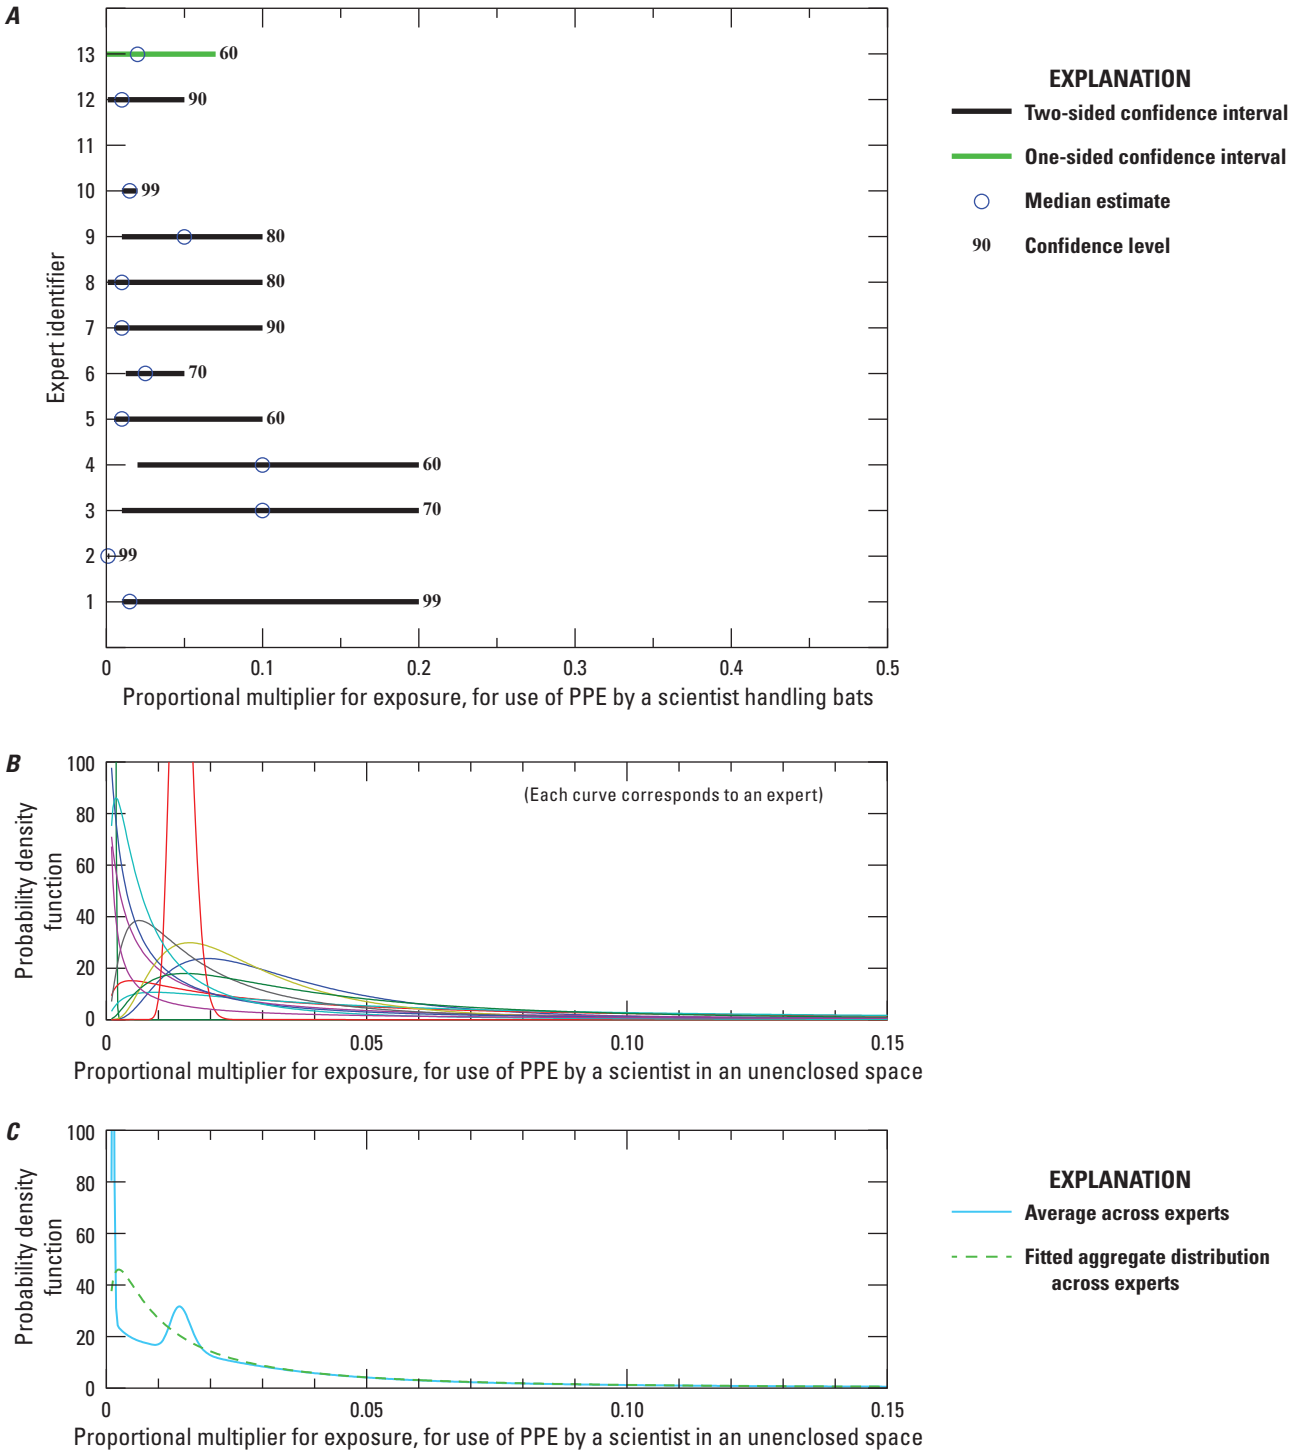

Figure 2.11. Expert panel responses to Question 11—multiplier for exposure, when using personal protective equipment, for a research scientist in an unenclosed space within 6 feet of bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 0.016 and an 80-percent confidence interval of (0.003, 0.096). PPE, personal protective equipment.

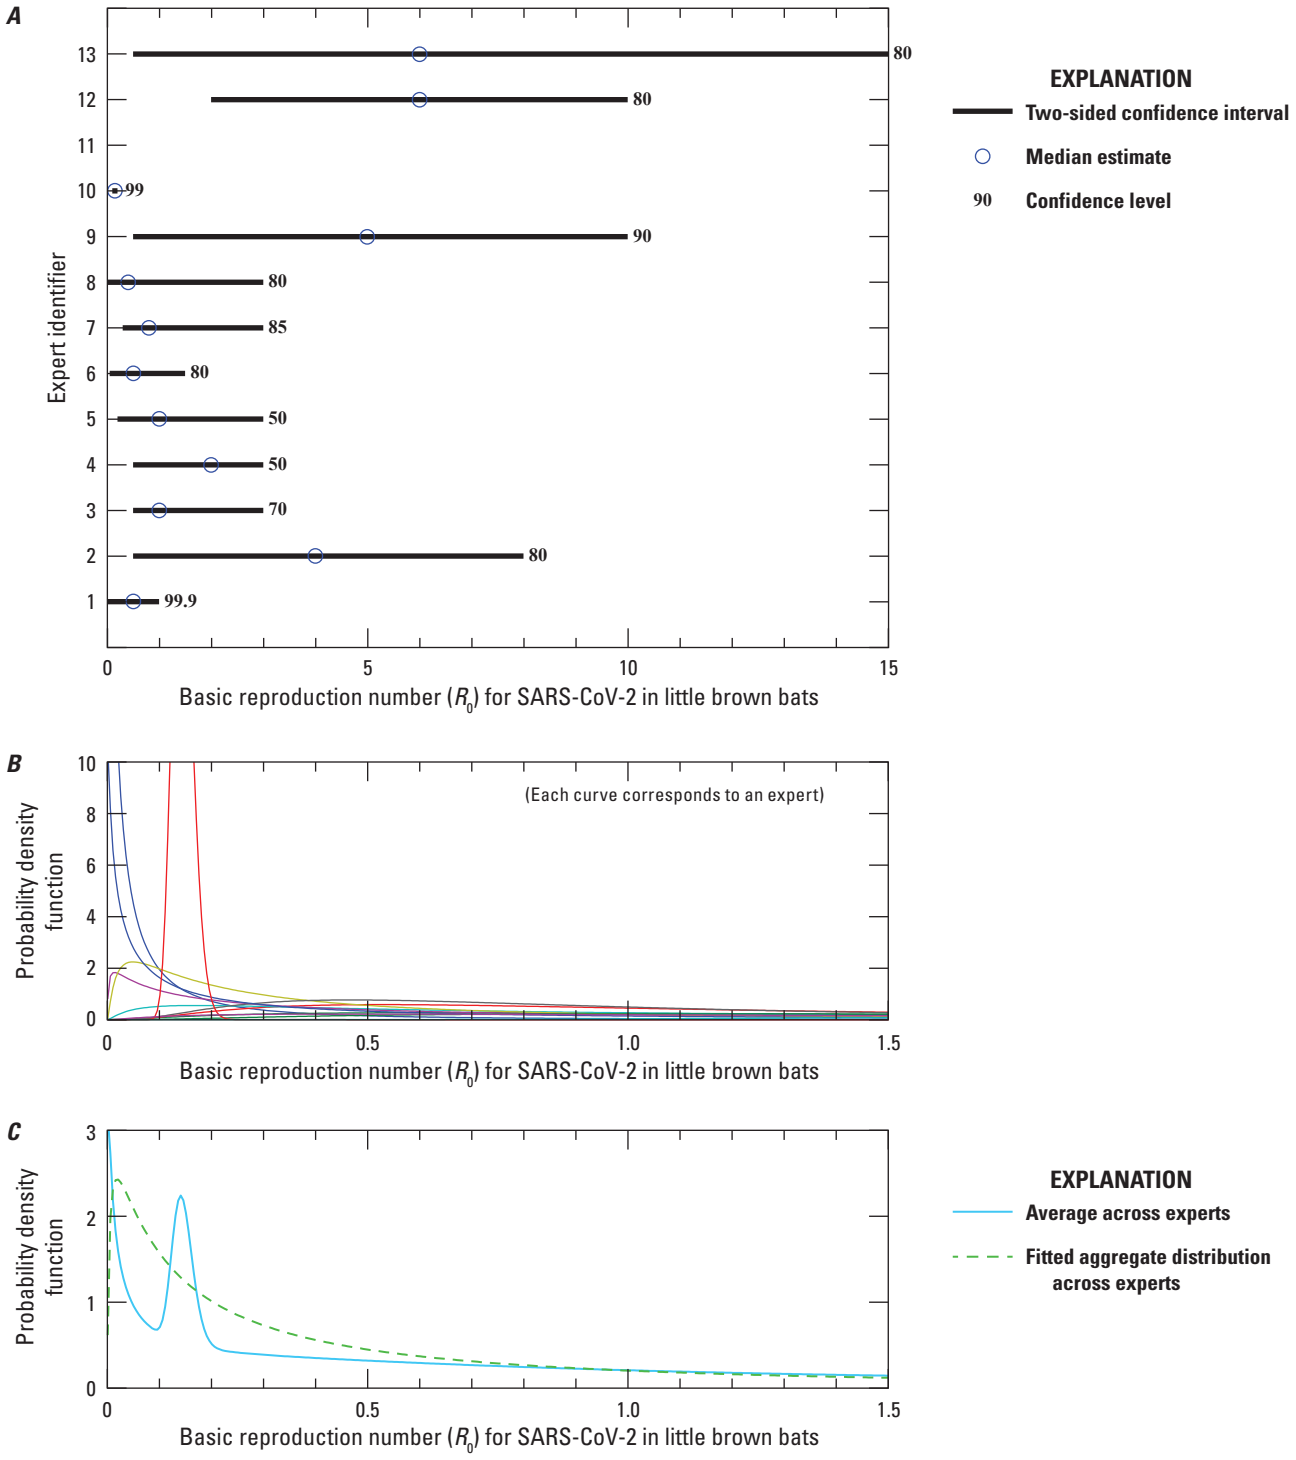

Figure 2.12. Expert panel responses to Question 13—SARS-CoV-2 R_0 in little brown bats. *A*, Four-point-elicitation responses from the individual experts, *B*, fitted probability distributions for individual experts, and *C*, average and fitted distributions across experts. The aggregate distribution has a median of 0.45 and an 80-percent confidence interval of (0.05, 4.38). In the aggregate distribution, the probability that R_0 is greater than 1.0 is 0.326.

Subject: SARS-CoV-2 spillback risk in North American bats

Hi Rebekah,

I got your email yesterday and will reply soon on that more-fun front, but here's a semi-spam message about the other stuff...

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. only on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot has happened during my silence. As you know by now, the USGS group led by Evan Grant and Mike Runge has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You were one of the dozen or so experts chosen for and actively participating in that exercise, so thanks for helping with that. I know from experience it can be a lot of work on an inconveniently compressed timeline, but think the immediate results will be very helpful to decision-makers faced with impending decisions about people interacting closely with bats. We may bug you about sources of state rabies lab data summaries at some point soon, so be forewarned and start flagging your emails from us as spam if you've already done your time! ☺

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of disease and bat researchers working together to draw on the strengths of our various disciplines. You've seen the long, rambling, unfocused version with the expert elicitation package, but its much more focused and concise now. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

Talk soon,
Paul

Subject: SARS-CoV-2 spillover risk to North American bats manuscript - FINAL version for PNAS (new plan)
Attachment(s): "smime.p7m"

Dear Co-authors,

Attached is the latest, submission ready version of our paper"**Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats**". Thank you all for the last round of invaluable edits and comments. Paul and I have now gone through multiple revisions since you last saw the paper in an attempt to include everyone's feedback; so apologize for the delay in turning this around and moving towards submission.

We started a submission to *Lancet Infectious Diseases*, but after thinking more about the journal's scope and reading other recent reviews that have been published in the journal, Paul and I decided it was not the best fit after all. We instead plan to submit this as a Perspectives article to *PNAS* (https://www.pnas.org/page/authors/purpose-scope). We think *PNAS* is a better fit all around, especially given the US focus of our review. We are currently following up some leads for "sponsorship" of our paper with PNAS which would make it an invited piece. If you have any specific suggestions in this regard, please let me know.

As before, the plan is once we submit (hopefully this week) to *PNAS* we will also post as a pre-print on BioRxiv so it can be viewed and used immediately. **If there are any objections to this plan or to submit to *PNAS*, please let me know.** Also, for those that have secured USG approval already, please let me know if these needs to be updated or if you need any more information.

This has been a fantastic exercise in group writing! Big thank you to everyone.

Cheers,
Kevin

Subject: World One Health Congress and BTRP TRN Side Meeting - BOHRN
Attachment(s): "WOHC and BTRP Side Meeting Schedule.pdf"

Dear BOHRN TRN Steering Committee Members,

On behalf of Dr. Martha Stokes, please accept this Save the Date to attend the World One Health Congress in Edinburgh, Scotland 15-17 June 2020 and participate in side meetings on BTRP's Threat Reduction Networks and planning for BOHRN.

Tentatively, we plan to hold two sessions at the end of the week: Thursday, 18 June - an afternoon TRN session that will include a wide group of BTRP-funded participants from its other research networks to discuss network metrics for sustainability; Friday, 19 June - a side meeting for BOHRN to map out its schedule and strategy, aligning with funding opportunities from BTRP and other entities. Attached is a tentative schedule for the week, for your reference. Due to travel and budgetary constraints we are unable to invite the entire steering committee, but intend to have productive discussions and meet objectives with the smaller group on this Save the Date email.

Please let us know if you will be able to attend the WOHC and side meetings on 18-19 June. Official invitation with travel instructions, details on arrangements, and more formal agenda will be forthcoming. Please note that there is a potential for the WOHC and BTRP side meetings to be postponed, given the current travel uncertainties related to COVID-19. We will be monitoring the status of the conference, and will keep you apprised of any cancellations should they occur. As always, let us know if you have any questions!

We hope to see you in Edinburgh!!

V/r,
Caitlin Devaney

Subject: Bat One Health Research Network Directory - request to join!

Dear BOHRN colleagues,

Oh my goodness, what a year it has been! We hope this message finds you all healthy and safe. While the pandemic has taken many of us on various detours from our usual routine and research over the past six months, we all have been very busy responding to this pandemic in myriad ways. In many cases, BOHRN network members have found ourselves working together on various initiatives, which has been exciting. We are looking forward to the time when we can interact in person again at conferences and at future BOHRN meetings. Thank you SO MUCH for all your efforts during this challenging time!

Tigga and I are writing to you today with a BOHRN-related update and a **specific action request to participate in a BOHRN membership directory (more details below)**.

The context: One of the positive outcomes of months of quarantine in Texas (Tigga) and Colorado (Rebekah) -- is that we followed up in a tangible way on one of the key challenges identified during our BORHN meetings: addressing the polarization of the bat ecology and infectious disease research communities. We have written a Perspectives piece, currently in review at PLOS Biology, which reports the results of a bibliometric analysis of co-author relationships among bat researchers between 1950 and 2019. This analysis identified a division between ecology- and infectious disease disciplines from the perspective of co-authored interdisciplinary journal articles (no surprise there!). However, our fields have done a good job at converging over issues that have presented a common mission, such as white nose syndrome. SARS-CoV-2 has provided a similar common ground for us to rally around as far as the risk this virus poses to both human and bat health. The editors and reviewers have challenged us to take steps that will actually lead to productive outcomes and interdisciplinary collaborations. Hence, we are very excited to engage directly with BOHRN and build on the infrastructure that has already been put into place by DTRA-BTRP.

Action item: In the immediate-term, **our goal is build a searchable membership directory housed within the BOHRN website.** This will enable members to connect with each other, learn more about what others are doing, and recruit people to the various working groups that BOHRN has established. DTRA and Global Systems Engineering have graciously and expeditiously revamped the website to enable this specific functionality. **How this works**: interested stakeholders will set up a member login on the BOHRN website as well as a member profile that will be visible to other members after logging in. **Members will benefit** from being able to search the directory for colleagues in complementary research areas, and receive information disseminated by BOHRN regarding opportunities and meetings. All of the information you enter will be accessible only to other members.

Steps we're asking you to take:

1. Go to https://www.bohrn.net
2. Click on "Join"
3. Create an account, fill out your profile
4. Check the boxes to affirm that you agree with having your information visible to others within the member page, and with the BOHRN mission statement (provided)
5. Click "Continue" to be brought to the Members page.
6. Your profile will automatically be entered into the directory, butthis may take a few hours to sync and be visible on the website.
7. From the Members page you should be able to view other member profiles as well as search the directory.

Thanks so much, and please don't hesitate to reach out to us if you have any questions. We look forward staying in contact and growing the BOHRN network together.

Kind regards,

Rebekah and Tigga

Subject: Bat One Health Research Network directory

Dear colleagues,

I hope this message finds you all healthy and safe. While the pandemic has taken many of us on various detours from our usual routine and research over the past six months, we all have been very busy responding to this pandemic in myriad ways. Thank you SO MUCH for all your efforts during this challenging time!

I'm writing to invite you to join the Bat One Health Research Network (BOHRN). BOHRN was formed in 2017 by the Defense Threat Reduction Agency Biological Threats Reduction Program (DTRA-BTRP) with the mission:

To convene a multidisciplinary consortium of disease researchers, conservationists, policy makers, and medical / veterinary practitioners into a network to characterize global threats of bat-borne pathogens and formalize community standards and conservation-conscientious practices for One Health disease research.

Tigga Kingston and I have been working with BOHRN to faciliate connecting researchers and other stakeholder groups with diverse, complementary expertise. O**ur goal is build a searchable membership directory housed within the BOHRN website.** This will enable members to connect with each other, learn more about what others are doing, and recruit people to the various working groups that BOHRN has established. DTRA and Global Systems Engineering have graciously and expeditiously revamped the website to enable this specific functionality (thank you!!). **How this works**: interested stakeholders will set up a member login on the BOHRN website as well as a member profile that will be visible to other members after logging in. **Members will benefit** from being able to search the directory for colleagues in complementary research areas, and receive information disseminated by BOHRN regarding opportunities and meetings. All of the information you enter will be accessible only to other members

If you're interested, please:

1. Go to https://www.bohrn.net
2. Click on “Join”
3. Create an account, fill out your profile
4. Check the boxes to affirm that you agree with having your information visible to others within the member page, and with the BOHRN mission statement (above)
5. Click “Continue” to be brought to the Members page.
6. Your profile will automatically be entered into the directory, butthis may take a few hours to sync and be visible on the website.
7. From the Members page you should be able to view other member profiles as well as search the directory.

Please feel free to spread the word, and encourage trainees/students/post-doctoral researchers on your teams to join!!

Thanks so much, and please don’t hesitate to reach out to us if you have any questions. We look forward staying in contact and growing the BOHRN network together.

Kind regards,

Rebekah

Subject: contact

Dear Kendra,

I hope this message finds you hanging in there ok during all of this! Thank you also for all your hard work on this North American bat paper! I've been interacting regularly with Tigga through the IUCN Bat Specialist Group and working on another paper; it's been nice keeping up with her outside of BOHRN. With everything going on with the bat research community and SARS-CoV-2 though, lots of BOHRN members are involved in various initiatives and and keeping pretty busy...someday when we are on the other side of this, I hope DTRA revitalizes a BOHRN meeting in person so we can all reconnect, debrief, and move some ideas forward that we had been discussing. I don't think anyone would accept another Zoom meeting at this point though!

Anyway, I'm writing to ask if I can put you in touch with a DVM/PhD student in my lab, Anna Fagre. Anna is outstanding, and interested in applying for one of the open positions at EcoHealth and just wants to do due diligence in finding out more about the position, expectations, etc. I thought of you as being a good person to provide some inside perspective, but wanted to reach out first to make sure that wouldn't put you in an awkward position, like if you're on the hiring committee or something.

Thanks so much!

Best regards,
Rebekah

Agreed, great job Kevin and Paul for the quick turnaround.

The CNN special can be viewed on www.cnn.com/go, click on “Shows” to the left-side of the screen and the special should be an option at the top of the screen (or one scroll to the right). I think you need a cable subscription to log-in to view though.

Cheers,
Kendra

Thanks Kevin and Paul for doing a great job so quickly.

I guess the CNN documentary yesterday also made this a hot (hotter) topic now and the editor may want to have “a ride on the bat wings” to get it out asap!

Fingers crossed.

Subject: Re: SARS-CoV-2 spillover risk to North American bats manuscript - FINAL version for PLOS Pathogens (new plan)

- External Email -

Hi Team,

Funny thing, bioRxiv actually rejected us! Apparently they don't take "reviews".

In any case we got **very positive reviews back from *PLoS Pathogens*** today, and the revised ms was just resubmitted (<24 hour turnaround). Woohooo! Finger's crossed that the editors turn it around again quickly and we can see this published soon.

Attached is the cover letter, response to reviewers, and the resubmitted version of ms.

Cheers,
Kevin and Paul

>
> Hume and Charlie, I understand your very valid and "traditional" concerns here, there's a lot of riff-raff out there on pre-print servers and hence why we have the peer-review system. Nonetheless, given that there are other similar reviews being posted at the moment and the timeliness of this given the USGS/USFW Risk Assessment out last week, etc., would be best to get this out there while we're still in review at PLOS.

Subject: Re: SARS-CoV-2 spillover risk to North American bats manuscript - FINAL version for PLOS Pathogens (new plan)

Dear all,

Update on our ms. It was submitted to PLOS Pathogens on June 2nd (you should have all received an email from the journal confirming this) and it is currently under review.

We are in the final stages of USGS approval to also submit to bioRxiv (pre-print server), and expect to finalize that and post it on bioRxiv in the next 24 hours. *Please let me know if there are any objections.*

Cheers,
Kevin

Thank you all for the last round of invaluable edits and comments. Paul and I have now gone through multiple revisions since you last saw the paper in an attempt to include everyone's feedback; so apologize for the delay in turning this around and moving towards submission.
> >
> > We started a submission to *Lancet Infectious Diseases*, but after thinking more about the journal's scope and reading other recent reviews that have been published in the journal, Paul and I decided it was not the best fit after all. We instead plan to submit this as a Perspectives article to *PNAS*(https://www.pnas.org/page/authors/purpose-scope). We think *PNAS* is a better fit all around, especially given the US focus of our review. We are currently following up some leads for "sponsorship" of our paper with PNAS which would make it an invited piece. If you have any specific suggestions in this regard, please let me know.

Dear colleagues,

Hot off the press! The IUCN Species Survival Commission Bat Specialist Group has released guidelines for researchers, to prevent the human-to-bat transmission of SARS-CoV-2. Our infographic is attached, and full guidelines available through either link below. Additional products are to follow shortly, tailored for other stakeholder groups. Please feel free to distribute as you see fit.

Best regards,
Rebekah

Preventing human-to-bat transmission of SARS-CoV-2

Exposure Risks

Contact exposure
Bats coming into contact with contaminated hands or equipment

Aerosol exposure
Infectious droplets from handlers holding bats in close proximity

Environmental exposure
Sharing enclosed, poorly-ventilated spaces with bats, where virus may persist in the air or on surfaces

MAP your plan to prevent transmission to bats!

Mitigation Strategies

Minimize

Delay, prioritize, or avoid handling bats when possible, i.e. implement acoustic surveys

Assess

Postpone handling bats if there is a probability that you have been exposed to SARS-CoV-2 or if you have symptoms

Protect

Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures

Subject: Re: [External Sender] RE: BOHRN Status, publication

Hi Katie, Marty, and Guzal -

Just chiming in to say hello and THANK YOU for the quick response and support for this effort! This is all great to hear, and I think we have a fantastic opportunity with this paper to provide another way to invigorate and draw attention to BOHRN. As Tigga and I were discussing the reviewer's suggestion, we basically converged on "Hey, BOHRN has already done all of this!" So it is wonderful to hear that we can move forward together to use this paper to direct people to BOHRN, which is where the rubber will hit the road. Looking forward to moving this forward, and we'll keep in touch with the revised manuscript. Thanks!

Best,
Rebekah :-)

Dear Marty
Thanks for the speedy response and support! Great to hear of the documentation efforts and continued commitment.

The lynchpin to everything that we'd like to do is the BOHRN website – is there a webmaster, or can one be allocated, so that we can host content, build membership, post some of the materials that have been developed.

Best
Tigga

Subject: RE: BOHRN Status, publication

Hi Tigga,

Congratulations on having your piece accepted (with revisions, as always)! I would really appreciate you adding detail about BOHRN and highlighting the network's efforts. All of the positive outcomes you mention are well noted and align with our goals and objectives, which remain steadfast.

The current situation has certainly created unexpected challenges for all our work, but we're adapting, and want to ensure that we continue moving forward and position the network to pick up where it left off last summer, once things return to a more normal environment. In the meantime, we'll do what we are able virtually.

Let us know what you need to support this. Katie and I, along with our teams, recently updated a huge amount of documentation, reports, participant lists, etc. for BOHRN and other our TRNs for the incoming BTRP Director, in order to deposit it on our internal database, so it should be very easy to provide whatever you need. Just let us know how we can help.

Thanks so much!

Best,
Marty

Subject: [External Sender] BOHRN Status, publication

Dear Marty,

Rebekah Kading and I wrote a perspectives piece that is in revision for PLOS Biology. It calls for greater integration of ecologists/virologists (hmm, sounds familiar) and builds on analysis of a publication coauthor network. We conceptualized this at BORHN meetings and consider it a true BOHRN output, supporting BOHRN's message.

One of the reviewers specified some simple, but concrete actions that they would like to see in the revision. These actions closely ally with things we've begun at BOHRN (e.g., mission statement, contact lists of researchers). We would really like to be able to respond using BOHRN's infrastructure as it would be a good fit and would draw substantial attention to BOHRN and help boost the distributed membership and get us more on the map. The reviewer called for a mission statement, a list of who is doing what, and other simple things that could easily be integrated into the BOHRN website.

Currently, we refer to BOHRN in the acknowledgements, but have been reluctant to feature the network too centrally because we are unsure of its status and stability. It would be great to move forward with BOHRN featured more prominently, but we could do with some clarity of where things are heading. At minimum we need support of the website as that is where we will be directing people. Currently people can't join, or reset passwords etc, and we would need to work with someone on updates supporting these simple collations of information.

We have a bit less than a month to turn this around and get our revision in, so it would be great to hear your thoughts. I hope we can talk soon. I am now free fairly consistently between 10 am-Noon Mo-Thursday. I have other windows here and there as well.

All the best

Tigga

Hi Kevin,

Very nice job on this! Only spotted a couple small things.
1) "highlights" is misspelled on line 128.
2) looks like a ref is still needed in line 342 regarding PPE usage in the field. This ref might fit...it's more broadly on wildlife professionals though (PMID: 31993824)
3) don't forget to delete the [...] on line 421

Yes, I would be delighted to be a co-author.

My ORCID is 0000-0002-4996-915X.

Thanks so much!

Subject: Final version of North American bat/SARS2 ms - PLEASE REVIEW

Dear Esteemed Colleagues,

Please review the attached penultimate draft of our manuscript (now entitled: **"Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats")**, together with the supplementary table and refs. Our plan is to submit to *Lancet Infectious Diseases* as a review article (correct length and they allow 150 refs) in the next week - references are currently formatted for that journal. We would also like to post it on bioRxiv as a pre-print once we get it submitted to *Lancet ID*. Please let me know if you have any concerns with that plan.

Thank you all for your excellent comments and edits on the previous draft. Paul and I have gone back and forth on several rounds of revisions since then (and multiple late night texts), aiming to take each and every suggestion into account, and we believe it's a much better manuscript now! Very excited about this one, and looking forward to getting it published!

By Thursday April 30th (or ASAP), could you each please:

1. Confirm that you agree to be a co-author.
2. Double check your name and affiliation, and send me your ORCID number if you have one.
3. Read through the ms and send any important, last minute changes or edits you feel are necessary. Please use track changes. If you're okay with the ms as is, please just confirm so.
4. For my Federal US Gov't friends (USFWS, USGS, CDC, USDA) - please let us know what we need to do for approval on your end. I know Paul is working with USGS now to hopefully get rapid clearance.

No need to cc all if you don't want, but please include both me and Paul on your response.

Looking forward to hearing from you all soon!

Cheers,
Kevin and Paul

Attachment(s): "Olival et al. Table S1_20200417_rck.xlsx"

Hi everyone -

Kevin and Paul - this manuscript is very good - thank you for putting it together!! I'll follow up later today with a few comments on the text. I want to read it again but have to go take care of our mosquito colonies at the moment...the one essential duty we have ongoing! I'm attaching the table in the meantime...very comprehensive, wow! I thought it might be helpful for readers to have a column with the broad geographic region of the coronavirus detection in each of the bats, so I added a column to cover this. In instances where the range of the bat species was fairly extensive, I went with where the sampling occurred in the paper. See if you like it...no worries if you don't think its necessary. A couple details/questions came up while I was working on that though:

- excel line 13 - *Nyctalus leisleri* is a European species but Tao and Tong sampled in Kenya...did they mis-identify or maybe there's an accidental reference error?
- excel line 22 - *Hipposideros pratti* looks like an Asian species but the Tao and Tong reference just sampled from Kenya
- excel line 49 - I changed this to Yinterochiroptera and colored it yellow

Question: Is it worth denoting on the table somehow where there is evidence of cross-species sharing of coronavirus strains? For example lines 44-45 the notes have "Eidolon_CoV" but the virus detections being reported were from *Scotophilus* and *Triaenops*...my interpretation is that the virus detected from those latter two bats was the same strain as was detected in *Eidolon* previously? Is there enough evidence to say anything about viral sharing (i.e. are full genomes available) or do we just leave that go for now? I was just thinking that it might be worthwhile to point out any propensity for transfer of strains between/among bat species because that would have relevance to NA bats too.

More later - thanks again - this is a very nice paper and impressive you put it together so quickly!

Hi Rebekah and Tigga,

Without further adieu, I'm attaching the manuscript draft that Kevin and I put together over the past week and would very much like your input on. Its much leaner and meaner than the rambling draft that went out to the decision-making group last week.

Please take a look if you have the time and consider joining us in trying to get it published somewhere fairly high profile in the coming weeks.

All the best,
Paul

Hi Paul, Kevin, Tigga,

I'll just reply to this thread. □ Yes, I'd be happy to take a look at the paper as well -- thank you very much for spearheading that effort! As Tigga mentioned we're working on something as well that we'll reach out to you guys separately about. Seems like BOHRN is mobilizing on multiple fronts, which is great to see.

Take care and talk to you soon -
Rebekah

Subject: RE: SARS-CoV-2 spillback risk to North American bats

Hi Paul
Very interested to see the MS. Rebekah and I have been working on something that arose out of BOHRN that would be very complementary and might be worth trying to coordinate dissemination in some way. We are meeting today and will take stock of where we are at.

I just started an email to you and Kevin about the state of affairs as we Rodrigo and I are getting quite a bit of push-back on the IUCN BSG recommendation to suspend field studies while further data are gathered (primarily from western scientists with access to PPE). It would be good to hear what those committees are finding sooner rather than later.

Best wishes
Tigga

Subject: SARS-CoV-2 spillback risk to North American bats

Hi Tigga,

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Hi Paul,

That's very kind of you to offer authorship - its unexpected and very generous of you, but I do appreciate being included! I'm attaching the text with some minor edits/suggests tracked for your consideration. Tigga's comments are great, and I'm glad to hear DeeAnn is involved as well.

Thanks!
Rebekah

Hi Rebekah and Tigga,

Thanks for the awesome and quick improvements to the manuscript. I'm assuming you're okay with being co-authors, cause you are now. ☺

I'm working through the comments from everyone now and will get back to you with thoughts about the more strategic and substantive ideas after I've had some time to think about them and catch up with myself.

In the meantime, one easy answer is that I see I created some confusion by citing Tao and Tong for Nyctalus leisleri and Hipposideros pratti in the supplemental table, which were actually reported by Drexler et al. 2010 (attached)...oops, good catch! I'll add country of origin to that table and flesh out the cross-referencing a little better for the next iteration.

And Tigga, thanks for those taxonomy updates! I didn't know about those changes, so thanks for that. DeeAnn is also looking at this and said she'd send a new table of the African pteropodid names, so I'm learning a lot.

Stay tuned and thanks again,
Paul

Subject: RE: [EXTERNAL] Re: SARS-CoV-2 spillback risk to North American bats

P.S. I looked at the table, and also spotted some things to check in addition to those high-lighted by Rebekah. Perhaps “Region” needs some clarification if it is where the bat was sampled – in the cases below it isn’t very representative of the distribution or was impossible

- *Rhinolophus ferrumequinum* is a Eurasian species, just tips into N. Africa
- https://en.wikipedia.org/wiki/Greater_horseshoe_bat

R. sinicus – predominantly Chinese bat -- doesn’t get in to Africa

https://en.wikipedia.org/wiki/Chinese_rufous_horseshoe_bat

Taxonomic updates:

FYI *Pteropus giganteus* is no more, it is currently recognized as *P. medius*

Eonycteris spalaea – spelling sp**e**laea

Note that the Hipposiderids have been broken with Rhinonycteridae elevated to family…

family **Rhinonycteridae**. elevated by Foley, *et al*, 2014.[2]
- genus *Cloeotis*
- genus *Brevipalatus*
- genus *Brachipposideros*
- genus *Paratriaenops*
- genus *Rhinonicteris* J.E. Gray, 1847
- genus *Triaenops*

So you might want to update the relevant species.

Best
Tigga

Subject: RE: [EXTERNAL] Re: SARS-CoV-2 spillback risk to North American bats

Hi Paul and Kevin

Great job, as Rebekah said.

I thought I'd give holistic feedback of possible gaps, inevitably based on commenting on the influence of ecology or at least species variability in possible risk. Despite the fact that you mention there are 40+ species at the beginning, this gets a bit lost and so we end up of perceiving "north American bats" as a single species. This is a trend that I've seen elsewhere in disease papers, in fact I read a risk perception paper recently that managed to get although way through without identifying a single species. It is relevant because, as we've seen with WNS, species have exhibited different responses and we could anticipate different spillback and transmission probabilities among species. This may be a function of differences in species-specific physiology but critically aspects of ecology (especially sociality/roosting ecology) and human-bat interface. So perhaps in the paragraph about interdisciplinary research you could highlight the diversity of bats and their ecology (not just numbers) and the consequences for interspecific differences in risk. (for eg. do you think Lasiurines are as at risk as Myotis?). The implications are essentially that there will never be a simple model system, and we must be very wary of extrapolating from single-species studies, but perhaps current knowledge of bat ecology in N Am (a pretty well known fauna compared to some parts of the world) in combination with virological, genomic and disease ecology expertise could be used to prioritize research.

This leads into whether there could be more strategic research recommendations to close out with. I like the suggestions in the final paragraph on how to implement research and useful contributions that could be made in the study of "north american bats". Closing out with possible priorities or a suggested strategy would make the document even more useful. For example, ensuring surveillance/discovery of the more synanthropic species, colonial species, or species already compromised by WNS, surveil widely across the N. Am phylogeny. Are there particular regions or contexts of N. America that should be the focus of efforts (species-rich caves, peri-urban and urban settings, species-rich geographic areas?). If that all seems too much to be definitive on, perhaps calling for cooperative development of a strategy with these as some suggested areas for consideration could be the way to go.

I think some consideration of the above would improve the MS and position it better in the research community as a springboard for more cohesive collaborative work. You want to guard against "we need more surveillance so give us funding" criticisms. Happy to help on that although my knowledge of N. Am bats is limited as you know, but could work on something about priority setting if you wish.

Minor point.. the SEABCRU link – that goes with the sentence below is actually a good example of how PPE guidance can be developed for ecologists/field researchers. It was based on a decision tree that reflects different contexts, and hence risks, that field biologists might find themselves. (great job Kevin…..) So it better illustrates that this can be done.

Hope this helps
Tigga
Xx

Subject: Re: [EXTERNAL] Re: SARS-CoV-2 spillback risk to North American bats

Hi everyone -

Kevin and Paul - this manuscript is very good - thank you for putting it together!! I'll follow up later today with a few comments on the text. I want to read it again but have to go take care of our mosquito colonies at the moment...the one essential duty we have ongoing! I'm attaching the table in the meantime...very comprehensive, wow! I thought it might be helpful for readers to have a column with the broad geographic region of the coronavirus detection in each of the bats, so I added a column to cover this. In instances where the range of the bat species was fairly extensive, I went with where the sampling occurred in the paper. See if you like it...no worries if you don't think its necessary. A couple details/questions came up while I was working on that though:

- excel line 13 - *Nyctalus leisleri* is a European species but Tao and Tong sampled in Kenya...did they mis-identify or maybe there's an accidental reference error?
- excel line 22 - *Hipposideros pratti* looks like an Asian species but the Tao and Tong reference just sampled from Kenya
- excel line 49 - I changed this to Yinterochiroptera and colored it yellow

Question: Is it worth denoting on the table somehow where there is evidence of cross-species sharing of coronavirus strains? For example lines 44-45 the notes have "Eidolon_CoV" but the virus detections being reported were from *Scotophilus* and *Triaenops*...my interpretation is that the virus detected from those latter two bats was the same strain as was detected in *Eidolon* previously? Is there enough evidence to say anything about viral sharing (i.e. are full genomes available) or do we just leave that go for now? I was just thinking that it might be worthwhile to point out any propensity for transfer of strains between/among bat species because that would have relevance to NA bats too.

More later - thanks again - this is a very nice paper and impressive you put it together so quickly!

Hi Rebekah and Tigga,

Without further adieu, I'm attaching the manuscript draft that Kevin and I put together over the past week and would very much like your input on. Its much leaner and meaner than the rambling draft that went out to the decision-making group last week.

Please take a look if you have the time and consider joining us in trying to get it published somewhere fairly high profile in the coming weeks.

All the best,
Paul

Subject: SARS-CoV-2 spillback risk to North American bats

Hi Tigga,

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Is there a risk of SARS-CoV-2 infection and transmission in North American bats?

Kevin J. Olival, Paul M. Cryan*, Kevin T. Castle, and multiple invited co-authors…*

*These authors contributed equally

Spillover and "spillback" of pandemic viruses

The threat of emerging infectious diseases (EIDs) to wildlife populations and biodiversity conservation is recognized (*1*), but cross-species transmission of novel pathogens, or spillover, is typically viewed in the narrow context of originating *from* a wildlife reservoir and transmitting *to* humans. Research assessing EID risk has focused on identifying geographic regions (*2, 3*) and wildlife species (*4-6*) where spillover of zoonotic diseases into human populations is most likely. Among recent pandemic viruses of zoonotic origin, some have no evidence of "spillback" to wildlife or domestic animal populations after they were established in people (e.g., HIV, which causes AIDS), and others cross species boundaries with fluidity (e.g. pandemic H1N1 Influenza A virus (*7, 8*)). Evidence of spillback, or reverse zoonosis, into wildlife and domestic animals is widespread (*9*), but viral spillback to wild bats has not been recorded. In December 2019, a novel coronavirus (now SARS-CoV-2) infected a cluster of humans in Wuhan, China and has since spread to become a global pandemic. The virus has reached over 185 countries, infected >2.1 M people, and killed >147,000. Phylogenetic evidence suggests that SARS-CoV-2, along with the entire clade of SARS-related coronaviruses (SARSr-CoVs), are zoonotic and evolved in Old-World bats from the family *Rhinolophidae* (*10-13*). The closest known virus to SARS-CoV-2 was discovered in *Rhinolophus affinis* from Yunnan province in China with 96% sequence similarity across the virus' genome (*14*), yet which proximate species led to human spillover remains unclear (*15*). The United States (US) is currently the epicenter of the largest recognized outbreak of COVID-19, with community transmission in all 50 states. The unintended consequences of this pandemic are many and include the possibility of SARS-CoV-2 spillback to free-ranging wildlife populations. Here we assess the possibility of SARS-CoV-2 spillback from humans to North American (NA) bats and discuss possible consequences of the virus becoming endemic in bats outside its natural host range.

The triple threat of SARS-CoV-2 to North American bats

The pandemic human spread of SARS-CoV-2 may threaten NA bat populations in three different ways. First, SARS-CoV-2 might infect and cause disease among the diverse and historically isolated 40+ species of temperate-zone NA bats. Second, SARS-CoV-2 might be able to infect and become established in one or more of these NA species, creating a diverse new suite of temperate-zone wildlife disease reservoirs. Third, if SARS-CoV-2 can persistently infect one or more species of NA bats, it could potentially evolve, or recombine with other endemic viruses, to become more pathogenic to humans and other mammals. The latter outcomes would undoubtedly shift public perception of bats from mostly beneficial wildlife with manageable associated disease risks, to bats as harmful nuisance animals posing unacceptable disease risks to human health. In addition to new public health challenges, such shifts could undermine decades of concerted science, conservation, and education efforts aimed at these important animals.

Lessons from an epizootic -- susceptibility of North American bats to introduced pathogens

SARS-CoV-2 is not the first pathogen that humans could inadvertently spread to NA bats. The COVID-19 pandemic follows the arrival of a fungal pathogen (*Pseudogymnoascus destructans*) that in 2007 began infecting NA populations, crossing species barriers, spreading among, and altering the evolutionary trajectory of the continent's bats (*16-19*). The disease of hibernating bats caused by that fungus, White-Nose Syndrome (WNS), remains the first and only documented bat epizootic (*20, 21*). WNS has killed millions of NA bats, affected populations of at least 12 species of 3 genera, and has already spread across half of the United States (US) and Canada. Methods of mitigating WNS spread and impacts remain elusive. It took years of concerted international scientific effort to first identify the novel cold-growing fungus, determine that it probably originated somewhere in the temperate zones of Europe or Asia, understand its mechanisms of infection and pathogenicity, and to track its rapid spread through an immunologically naïve continental assemblage of hibernating bats that lacked many defenses against it (*22*). The devastating impact of WNS on a diverse group of NA bats likely resulted from evolutionary isolation of the continent's bat fauna from large parts of the world for millions of years. Bats in both Europe and Asia can become infected by *P. destructans*, but do not suffer mass mortality from WNS (*23, 24*). No extant species of bat that occurs in the Americas also occurs outside of the Americas (*25, 26*), and no bat species regularly migrates or likely survives flights across the Pacific or Atlantic oceans (*27, 28*). The bat fauna spanning the higher latitudes of NA (e.g., US and Canada) is composed almost entirely of species belonging to the world's largest bat family -- Vespertilionidae. Vespertilionid bats occur all over the world, but likely originated and diversified in NA tens of millions of years ago -- they are the only bat family to increase in diversity northward out of the tropics and consistently reach high latitudes (50ºN;(*29, 30*). The WNS epizootic taught us that a large proportion of this historically isolated bat fauna can be vulnerable to pathogens introduced from other continents. Additionally, bats already in a physiologically stressed condition due to WNS or other pressures may have increased susceptibility to viral infection, experience exacerabated disease outcome, and/or increased viral shedding (REFS). The COVID-19 pandemic invokes the specter of WNS and highlights deficits in our understanding of pathogens in NA bats.

Gaps in understanding global patterns of bat-CoV diversity and evolution

Bats are among the most diverse mammals (approximately 1,400 species), and global distributions and diversity of CoVs in bats proportionally reflects that of their hosts (*31, 32*). Bats also rank among the most ecologically important but underappreciated mammals that play varied roles in most of Earth's ecosystems (*33, 34*). Coronaviruses appear to have ancient and ancestral relationships with bats, diversifying globally through a process of within-host evolution and cross-taxonomic host-switching events (*31, 35, 36*). Available evidence indicates that bats are natural reservoirs of CoVs with pre-emergent potential to cause diseases in humans, livestock, and other types of domestic animals and wildlife (*14, 31, 37-50*). Indeed, bats are the likely progenitor hosts of all alpha (α-) and beta (β-) CoVs (*51*) and potentially all *Coronaviridae* (*52-57*). Two recent human disease epidemics (Severe Acute Respiratory Syndrome [SARS], Middle East Respiratory Syndrome [MERS]) and now the COVID-19 pandemic were caused by

viruses that probably originated from CoVs circulating in populations of wild bats near the outbreak origins (*14, 38-43, 49, 50, 58, 59*). A similar CoV of likely bat origin also recently caused Swine Acute Diarrheal Syndrome (SADS) outbreaks and mass mortality of piglets on farms in Guangdong province, China (*46*). Emergence of diseases like SARS, SADS, and now COVID-19 from the same general region strongly indicates a close association between CoVs likely to evolve into pathogens and the wildlife reservoirs where they originate (*14, 38-43*). Bat CoVs show clear global patterns of geographic structure that reflect host distributions, and typically strong co-evolutionary patterns among related hosts (*31, 49, 60, 61*). These phylogeographic factors are also universal determinates of viral sharing among all mammals (*62*). However, predicting broad CoVs jumps (i.e., that lead to spillover and spillback) is difficult because of the wide potential host breadth for many CoVs (*13, 44, 45, 63-67*), and the fact that bats are often asymptomatic reservoirs capable of harboring a diversity of CoV lineages -- obscuring bat-virus association patterns (*31, 49, 50, 61, 68*). Bat-CoV associations remain woefully understudied in temperate-zone NA, despite the large number of bat biologists and virologists working in the US, Mexico, and Canada (*31, 68-70*).

Are viruses like SARS-CoV-2 already widespread in North American bats?

Our preliminary examination of CoV evolutionary lineages and global distribution patterns of the diverse bats they infect suggests that NA bats could be immunologically naïve to infection by viruses like SARS-CoV-2. Alpha and β-CoVs have been detected in bats on most continents, sometimes with both types occurring in the same bat species and individuals (*49, 50, 71*). However, a striking exception to this pattern is the apparent lack of evidence that β-CoVs infect bats of temperate-zone NA. Multiple novel α-CoVs have been detected and described in Nearctic vespertilionid bats of the US and Canada, infecting species living in close contact with humans and in remote wild areas (*68, 70, 72*). Alpha-CoVs ~~of~~ likely of bat origin can cause disease in humans and other animals including human α-CoVs NL63 and 229E (*73, 74*). However, emerging infectious diseases like MERS, SARS, SADS, and COVID-19 are caused by β-CoVs. Therefore, scientists have focused great effort on detecting, genotyping, studying the geographic distribution, and host-cell receptor binding of β-CoVs in bats (*49, 50*). SARSr-CoVs of the viral subgenus *Sarbecovirus* that can bind to angiotensin-converting enzyme 2 (ACE2) host-cell receptors of humans and other animals have thus far been detected mostly in species of the Old-World Chiropteran suborder Yinpterochiroptera (Table S1; Fig. 1A; (*11, 31, 49, 50, 75-79*). Two exceptions to this pattern were detection of novel Clade 3 and Clade 1 *Sarbecovirus* (*sensu* (*41*)) in the bat *Chaerephon plicata* (family Molossidae) in China (*80*) and the vespertilionid species *Nyctalus leisleri* cohabiting a Bulgarian cave during autumn with several species of *Rhinolophus* in which other SARS-related β-CoVs were concurrently detected (Fig. 1A; (*81*). β-CoVs of other distinct evolutionary lineages, such as viral subgenera *Hibecovirus* and *Nobecovirus*, also tend to occur mostly in Old-World bat families, with the exception of novel viruses of the latter subgenus detected in two species of *Scotophilus* in Africa (Fig 1B, C; (*31, 41, 49, 50, 77, 82*). Bat β-CoVs of the subgenus *Merbecovirus* (MERS-related lineage) occur in a greater diversity of bat families and across more global regions than others (Fig. 1D; (*49, 60*). These widely distributed viruses can evolve to cause disease in humans and animals (e.g., MERS) and notably appear to be the only bat β-CoVs to diversify among several families of the globally distributed suborder Yangochiroptera (Fig. 2; (*49, 50, 76-78, 83-87*). The several hundred species of extant bats spanning the Americas all belong to the suborder

Yangochiroptera, which likely diverged from the Old-World Yinpterochiroptera more than 50 million years ago (Fig. 2; (*88*)). In the Americas, a novel β-CoV of the subgenus *Merbecovirus* was detected in *Nyctinomops laticaudatus* (family Molossidae), and other distinct lineages in the subgenus *Merbecovirus* were described from *Pteronotus davyii* and *P. personatus* (family Mormoopidae), as well as species of *Artibeus* and *Dermaneura* (family Phyllostomidae) from tropical regions of Mexico (*31, 89, 90*); none of these bat species occur outside of the Neotropics. Successful *in vitro* infection of cells from the Neotropical bat *Artibeus jamaicensis* with MERS-CoV led to experimental infection trials that resulted in virus replication and shedding without obvious clinical signs of disease (*91*). Considering these laboratory findings and detection of only β-CoVs of the subgenus *Merbecovirus* in two exclusively Neotropical bat families (Phyllostomidae & Mormoopidae) and one that is globally distributed (Molossidae), available evidence suggests β-CoVs may have arrived to the New World through South America and have long been evolving in Neotropical bats. β-CoVs of the subgenus *Merbecovirus* are not known to target ACE2 cell receptors, instead using the dipeptidyl peptidase-4 (DPP4/CD26) or possibly other receptors (*41, 92*). Assessing SARS-CoV-2 host range using virus-host receptor binding assays *in silico* and *in vitro* (*14, 41, 92, 93*), together with future experimental infection studies for 'gold standard' confirmation, hold promise to better quantify the potential for NA bat infection. We are not aware of any published detections of β-CoVs in temperate-zone NA vespertilionid bats, although sampling has been limited. Overall, proportionally few studies have looked for CoVs in the approximately 1,400 species of bats occurring across six continents. This sampling deficit limits the inference obtainable by examining known patterns of bat-CoV occurrence and distribution. To our knowledge SARSr-CoVs (*Sarbecovirus spp*; (*41, 77*)) have only been detected in one species of vespertilionid bat in Bulgaria (*81*), a likely transmission from co-roosting *Rhinolophus* sp. bats. This absence of evidence for β-CoVs in temperate-zone bats of NA leaves important gaps in our ability to gauge threats posed by SARS-CoV-2 to bats in the US and Canada.

Figure 1. Global patterns of bats and associated beta-coronaviruses (β-CoVs). A) red-shaded distributions of bat species in which SARS-related β-CoVs of the viral subgenus *Sarbecovirus* were detected; B) pink-shaded distributions of bat species known to host β-CoVs of the subgenus *Hibecovirus*; C) brown-shaded distributions of bats in which β-CoVs of the *Nobecovirus* lineage have been detected; and D) green-shaded distributions of bats known to host MERS-related β-CoVs of the subgenus *Merbecovirus*. Different colors and shade styles within each panel represent different families of bats. See Table S1 for species lists. Maps created using ArcMap (ESRI, Redlands, California, USA) and bat ranges derived from spatial data on terrestrial mammals from the IUCN (https://www.iucnredlist.org/resources/spatial-data-download).

Proactively connecting the wellbeing of human and bat populations

Scientists have long recognized the risk of disease spillback from humans to bats (*94-96*), but bat researchers in NA did not systematically address such risk prior to WNS**.** Few bat

researchers studied infectious diseases ~~in~~ of bats before WNS emerged in 2007 (*69*) and proportionally few disease researchers studied bat pathogens before bats were retrospectively connected to the SARS epidemic (*12, 58, 97*). An often unstated duality of such disease responses is the seemingly contradictory facts that bats are unequivocally ecologically important (*33, 34*), yet also a diverse source of emerging infectious diseases (*6, 50, 97-101*). Factors driving the ecologic success of bats are often the same as those invoked for explaining why bats might host such a diversity of viruses. These factors include characteristics of bat life history (e.g., long-lived, slow reproducing, wide dispersal, multi-species aggregations, daily and seasonal torpor (*97*)), unique physiology for repairing damaged DNA (*102*), unique ability to regulate immune response (*103-105*), and unmatched metabolic range and high body temperatures during flight (*106*). Bats also cryptically come into closer contact with humans than many other types of wildlife, often daily crossing human-wildlife interfaces. An oft-overlooked flip side to abundant evidence that many dangerous human diseases originate from bats is the fact that bats rarely show signs of mass mortality and sickness from these same dangerous pathogens (*20*). Bats cope with viral infection in ways that we do not yet fully comprehend but learning how they do so may reveal important insights to develop therapeutics and ultimately protect human health. *In vitro* and laboratory studies demonstrate that bats can regulate immune response to effectively cope with MERS-CoV and SARS-CoV-2 infection, at least under experimental conditions (*104, 107*). Lack of clear signs of sickness in bats and the cryptic habits of many species also generally inhibit our ability to easily detect spillback of pathogens from human to bat populations, further adding to uncertainty about movement of CoVs among groups. Laboratory findings suggest human viruses like HCoV-NL63 may have historically moved back and forth between human and bat populations multiple times (*74*). SARS-CoV-2 and other CoVs are relatively long for RNA viruses, making them susceptible to recombination and copy errors with resulting functional adaptations (e.g., receptor binding ability, temperature adaptation enzymes)(*108*). CoVs can recombine with functional fragments of other virus families, such as when a bat-derived CoV gained a functional gene from a reovirus (*109*). If spillback of SARS-CoV-2 into NA bats led to the virus becoming more pathogenic to bats, domestic animals, or humans through genetic mixing in a NA bat reservoir host, the public-health and conservation consequences would be severe.

Need for an interdisciplinary disease response

Effectively managing risks of human disease caused by emerging zoonotic pathogens *and* ensuring the health and conservation of potential wildlife reservoirs of those disease agents are not mutually exclusive goals. Research has shown that spillover risk (and probably spillback risk) may be highest in disturbed ecosystems where there is a high frequency of human-wildlife interactions (*2, 110, 111*). Thus, effective bat conservation and management requires understanding both pathogens that cause disease in bats, as well as human activities that present health risks in environments we share with bats. Furthermore, seemingly intuitive reactions to disease risk from wildlife, such as culling infected bat populations, often have negative unintended consequences for the interconnected health of both human and bat populations (*112, 113*). Temperate-zone vespertilionid bats inhabiting human dwellings in US and Canada represent a particularly relevant human-wildlife interface where such actions and potential consequences for disease spillback and spillover may be particularly worth careful consideration. A growing field of 'One Health' or conservation-minded bat virus research studies

have demonstrated the potential for mutual benefit of collaboration between public health, disease, and conservation stakeholders (*95, 112, 114-119*). Disease-focused studies that integrate ecological principles into a rigorous study design provide the most ecologically-relevant context to the pathogen findings. ~~For example~~Additionally, proper use of personal protective equipment (PPE) including respiratory protection has been adopted by the bat virus research community but by few others studying bats. Assessing the risks of SARS-CoV-2 spillback into NA bats ~~seems like a perfect~~presents a timely opportunity to integrate and practically apply lessons learned from prior epizootic and pandemic disease responses, and to tap a growing field of CoV experts studying viral transmission, host range, and natural history. Free-ranging bats are notoriously difficult to study, so scientists researching EIDs can benefit from methods bat researchers have developed for observing, counting, and non-invasively sampling bats (*69, 120*). Bat researchers can learn important biosafety, health monitoring, and laboratory techniques from researchers with expertise in veterinary and medical sciences (*117, 118*).

SARS-CoV-2 alters the *status quo* of bat research, emphasizing the need to carefully weigh risks and benefits of wildlife research in the context of population-altering diseases (*121*). Adopting a precautionary approach in the face of widespread COVID-19 transmission, US and international wildlife organizations have begun advising limiting field research to minimize the risk of humans infecting bats with SARS-CoV-2 until further assessment can be made (*122, 123*). A rapid, quantitative risk assessment and analysis of various mitigation options is an urgent research priority and is currently underway (*122*). One key question is if the proper use of PPE and masks, together with other basic biosafety practices (*124*), during field work can significantly reduce the risk of transmission to bats. In the interim, until new guidelines are established for handling and near-proximity work with bats, important scientific inquiry could continue. Temporarily shifting to 'hands-off' bat research methods in temperate-zone NA seems prudent wherever possible. Examples of such methods applicable to both disease and conservation research include: monitoring echolocation calls to determine the occurrence, distributions, and seasonal/nightly activity patterns of bats (*125-128*); digital imaging methods for counting bats and studying physiology and behaviors in the context of disease and anthropogenic landscape change (*19, 129-134*); methods of safely attaching tracking tags and environmental sensors to bats for multi-month periods (*19, 135*); and sampling guano from below bat roosts to determine bat species and individual identity, population dynamics, and daily or seasonal patterns of bat occupancy and pathogen shedding (*68, 136-139*). Promising areas for innovation include making these 'hands off' field technologies more accessible to a broader global user base, less expensive, easier to use, and scientifically reproducible through open-source hardware, software, and laboratory methods (e.g., (*140-146*)). Assessing the risk of SARS-CoV-2 transmission to NA bats also raises critical gaps in knowledge about bat CoV diversity and distribution, particularly in the New World. Standardized field protocols and probabilistic sampling strategies for monitoring bats and their viruses at a continental scale are needed (www.nabatmonitoring.org; (*147-149*). The currently unknown but potentially high-consequence risk of SARS-CoV-2 transmission and establishment in NA bats warrants precaution. We are at a critical nexus of biosecurity and natural resource conservation. Our actions during this current pandemic could profoundly influence the health of both human and bat populations.

Hi Paul, Kevin, Tigga,

I'll just reply to this thread. □ Yes, I'd be happy to take a look at the paper as well -- thank you very much for spearheading that effort! As Tigga mentioned we're working on something as well that we'll reach out to you guys separately about. Seems like BOHRN is mobilizing on multiple fronts, which is great to see.

Take care and talk to you soon -
Rebekah

Subject: RE: SARS-CoV-2 spillback risk to North American bats

Hi Paul
Very interested to see the MS. Rebekah and I have been working on something that arose out of BOHRN that would be very complementary and might be worth trying to coordinate dissemination in some way. We are meeting today and will take stock of where we are at.

I just started an email to you and Kevin about the state of affairs as we Rodrigo and I are getting quite a bit of push-back on the IUCN BSG recommendation to suspend field studies while further data are gathered (primarily from western scientists with access to PPE). It would be good to hear what those committees are finding sooner rather than later.

Best wishes
Tigga

Subject: SARS-CoV-2 spillback risk to North American bats

Hi Tigga,

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Hi Rebekah and Tigga,

Without further adieu, I'm attaching the manuscript draft that Kevin and I put together over the past week and would very much like your input on. Its much leaner and meaner than the rambling draft that went out to the decision-making group last week.

Please take a look if you have the time and consider joining us in trying to get it published somewhere fairly high profile in the coming weeks.

All the best,
Paul

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Hi Rebekah,

Is there any way we could get a draft of the manuscript? We would maintain confidentiality and keep it close hold.

Thanks so much.

Best,
Marty

Hi Katie, Marty, and Guzal -

Just chiming in to say hello and THANK YOU for the quick response and support for this effort! This is all great to hear, and I think we have a fantastic opportunity with this paper to provide another way to invigorate and draw attention to BOHRN. As Tigga and I were discussing the reviewer's suggestion, we basically converged on "Hey, BOHRN has already done all of this!" So it is wonderful to hear that we can move forward together to use this paper to direct people to BOHRN, which is where the rubber will hit the road. Looking forward to moving this forward, and we'll keep in touch with the revised manuscript. Thanks!

Best,
Rebekah :-)

Hi, Tigga. Guzal (copied) should be able to help. I can make sure she has all the passwords; give us a day to make sure all the links are active. I talked with her today about it and she is ready to support in any way.

Dear Marty

Thanks for the speedy response and support! Great to hear of the documentation efforts and continued commitment.

The lynchpin to everything that we'd like to do is the BOHRN website - is there a webmaster, or can one be allocated, so that we can host content, build membership, post some of the materials that have been developed.

Best

Tigga

Subject: RE: BOHRN Status, publication

Hi Tigga,

Congratulations on having your piece accepted (with revisions, as always)! I would really appreciate you adding detail about BOHRN and highlighting the network's efforts. All of the positive outcomes you mention are well noted and align with our goals and objectives, which remain steadfast.

The current situation has certainly created unexpected challenges for all our work, but we're adapting, and want to ensure that we continue moving forward and position the network to pick up where it left off last summer, once things return to a more normal environment. In the meantime, we'll do what we are able virtually.

Let us know what you need to support this. Katie and I, along with our teams, recently updated a huge amount of documentation, reports, participant lists, etc. for BOHRN and other our TRNs for the incoming BTRP Director, in order to deposit it on our internal database, so it should be very easy to provide whatever you need. Just let us know how we can help.

Thanks so much!

Best,

Marty

Subject: [External Sender] BOHRN Status, publication

Dear Marty,

Rebekah Kading and I wrote a perspectives piece that is in revision for PLOS Biology. It calls for greater integration of ecologists/virologists (hmm, sounds familiar) and builds on analysis of a publication coauthor network. We conceptualized this at BORHN meetings and consider it a true BOHRN output, supporting BOHRN's message.

One of the reviewers specified some simple, but concrete actions that they would like to see in the revision. These actions closely ally with things we've begun at BOHRN (e.g., mission statement, contact lists of researchers). We would really like to be able to respond using BOHRN's infrastructure as it would be a good fit and would draw substantial attention to BOHRN and help boost the distributed membership and get us more on the map. The reviewer called for a mission statement, a list of who is doing what, and other simple things that could easily be integrated into the BOHRN website.

Currently, we refer to BOHRN in the acknowledgements, but have been reluctant to feature the network too centrally because we are unsure of its status and stability. It would be great to move forward with BOHRN featured more prominently, but we could do with some clarity of where things are heading. At minimum we need support of the website as that is where we will be directing people. Currently people can't join, or reset passwords etc, and we would need to work with someone on updates supporting these simple collations of information.

We have a bit less than a month to turn this around and get our revision in, so it would be great to hear your thoughts. I hope we can talk soon. I am now free fairly consistently between 10 am-Noon Mo-Thursday. I have other windows here and there as well.

All the best

Tigga

Title: Suiting up for a common cause: interdisciplinarity in bat disease research

Short title: Interdisciplinarity in bat disease research networks

Authors: Rebekah C. Kading[1]*, Tigga Kingston[2]

Abstract: Human perturbation of natural systems is accelerating the emergence of infectious diseases, mandating integration of disease and ecological research. Bats have been associated with recent zoonoses, but bibliometric analysis of co-author relationships identified a separation of bat ecologists and infectious disease researchers with few cross-disciplinary relationships. However, research with outcomes for both bat conservation and disease mitigation promoted integration and network connectivity. We advocate for increased engagement between ecology and infectious researchers to address such common causes. We suggest that efforts focus on leveraging existing activities, building interdisciplinary projects, and networking individuals and networks to integrate domains and coordinate resources.

Introduction

Many months into the COVID-19 pandemic, the pathway to emergence has yet to be characterized. This is not unusual; understanding disease emergence requires integration of expertise from diverse domains in complex ecological and epidemiological contexts (1). Although such interdisciplinarity is central to One Health frameworks (2), Manlove et al. (3) demonstrated that too often the requisite expertise is siloed, limiting integrative understanding of complementary fields. Here, we focus specifically on the bat research and conservation communities, in which historical silos are now challenged by the emergence of SARS-CoV-2. The virus threatens both human and bat health, thus requiring interdisciplinary cooperation in a realm that has been historically fraught with emotion and mistrust.

Trouble in Gotham City

With more than 1400 species, bats are a critical, yet highly vulnerable, component of ecosystems worldwide (4). Bats have also been implicated in the emergence of notable zoonoses. Although emergence has been well-characterized for some bat-origin zoonoses (e.g., Nipah, Hendra, SARS, Marburg), it is unclear how others have emerged, as with Ebola and now SARS-CoV-2 (5). Advancing the missions of bat conservation and public health protection have seemed, to many, to conflict. This has led to entrenched positions, with accusations of alarmist risk inflation to support funding of viral discovery on the one hand, and denial or down-play of the role of bats in emerging infectious diseases on the other. Media representation has further polarized positions, with emotive headlines that refer to bats as, for example, “breeding grounds of deadly diseases” or “the number-one carrier of disease”.

It is our contention that the integrative research needed to characterize emergence is hampered by limited effective communication and collaboration between bat ecologists and disease researchers. We undertook a bibliometric analysis of co-author relationships to investigate the

extent of cross-disciplinary collaboration between ecological- and infectious disease-oriented bat researchers (See Supplementary Methods).

The View From the Bat Cave

Consistent with previous findings (3), our analysis revealed a clear boundary between authors representing disease- and ecology-focused disciplines (Fig 1), and there were distinct clusters within disciplines. Discipline-specific expertise is the bedrock of collaborative research, so disciplinary clusters of productive research groups are expected and needed (6). However, qualified disciplinarians with strong social networks are also central to interdisciplinary success (2), and need to lead and encourage cross-disciplinary collaborations.

A few influential (betweenness centrality >500), "boundary-crossing" authors have published with colleagues both inside and outside their primary discipline (Fig 1: authors "A" from disease and "B" from ecology), but other influential authors, while extraordinarily productive and connected within their own fields, did not reach outside of their discipline (Fig 1: "C" in disease and "D" in ecology).

Suiting Up For a Common Cause

So how can we join forces to advance the field in the most integrative way? One motivation that emerged from our analysis was a common goal; common goals that motivate and engage researchers can help overcome institutional, cultural and trust barriers (6). In our analysis, integrative interdisciplinary relationships were exemplified by an international cluster that focuses on the ecology, pathology and physiology of White Nose Syndrome (WNS), a disease resulting from a fungal infection that has killed millions of bats in North America since it was first detected in 2006. The WNS cluster (blue/orange in Fig 1) meanders throughout the network and crosses disciplinary lines and, because of the diverse membership, bridges both disease and ecology clusters (red, purple, dark green).

Just as WNS has provided common ground for convergent research, understanding and mitigating other emerging zoonoses with One Health implications, like SARS-CoV-2, involve common challenges that are best met through cross-disciplinary engagement. This engagement can range from robust data collection for a complementary discipline (**leveraging**), to interdisciplinary projects designed collaboratively from the ground-up (**building**), to research networks that actively aim to integrate domains and resources (**networking**):

1) **Leveraging.** Existing research programs can leverage expertise to further specific or common agendas. For example, bat taxonomists and systematists could work alongside pathogen surveillance teams to integrate biodiversity expertise and infrastructure more effectively into virus discovery and mitigation efforts (7). Many viral discovery papers do not identify bat hosts to the species level, either because the researchers lack appropriate training and/or because the taxonomy of the sampled bats is not clearly defined. Bat diversity of many regions of biosurveillance interest is poorly known, with unresolved taxonomy of species-rich groups and likely many undescribed species. Greater bat survey and taxonomic effort is both central to effective bat conservation (8), and needed to draw correct associations between pathogen and host.

2) **Building.** Building new integrative research areas that are foundational to both research domains provides strong motivation for collaboration. For example, the question " What is a sick bat?" is central to global discussion of the ability of bats to harbor infectious agents that are highly pathogenic to people, but with [usually] little apparent health impact to themselves. Understanding bat health is directly relevant to infectious disease research and may provide important biomedical insights regarding infection tolerance. Stress induced by human disturbance or environmental modifications also threatens species conservation and management (4). Even sublethal stress can erode bat health and fitness and influence pathogen shedding and infection dynamics (9,2).

3) **Networking.** Networking individuals and existing research networks accelerate transfer of knowledge and expertise, and allow for prioritization and coordination of activities and key resources (10). Many ecologists within our co-author network have access to long-term study sites, or wild study populations, with years and sometimes decades of relevant data on ecology, life history, genetic relationships, responses to disturbance regimes, etc. These established sites and populations could provide settings for virological studies across ecological and conservation contexts. Additionally, numerous scientific questions can only be rigorously addressed with the use of captive bat colonies. Such colonies are few but distributed across the co-author network in support of research that ranges from the biomechanics of flight and the evolution of sociality, to experimental challenges with infectious agents to determine susceptibility and disease dynamics relevant to human or bat health. Thoughtful discussions and exploration of non-invasive or minimally invasive contributions that can be made by colonies held for non-disease research are needed. Ideally, networking of existing colonies could facilitate access to colonies) from each bat family, and generate associated primary cell lines, genomic, and transcriptomic data. Alignment of experimental protocols would further facilitate the comparison of biological phenomena, including susceptibility and responses to pathogens, across taxa, and the parameterization of models.

Up Up and Away!

We considered connectivity and divisions in disease and bat ecology research communities. Similar divisions likely exist between ecologists and disease researchers focused on other taxa that harbor zoonotic pathogens, such as rodents (hantaviruses and arenaviruses), birds (influenza viruses), non-human primates (retroviruses), and wild ungulates (prions). We suggest that interdisciplinary research can be accelerated when disparate domains address common, foundational causes through some combination of leveraging, building and networking.

All authors have read and agreed to the published version of the manuscript; Competing interests: Authors declare no competing interests; and Data and materials availability: All data

and analytical procedures are available in the main text. Figure 1 was created using BioRender.com.

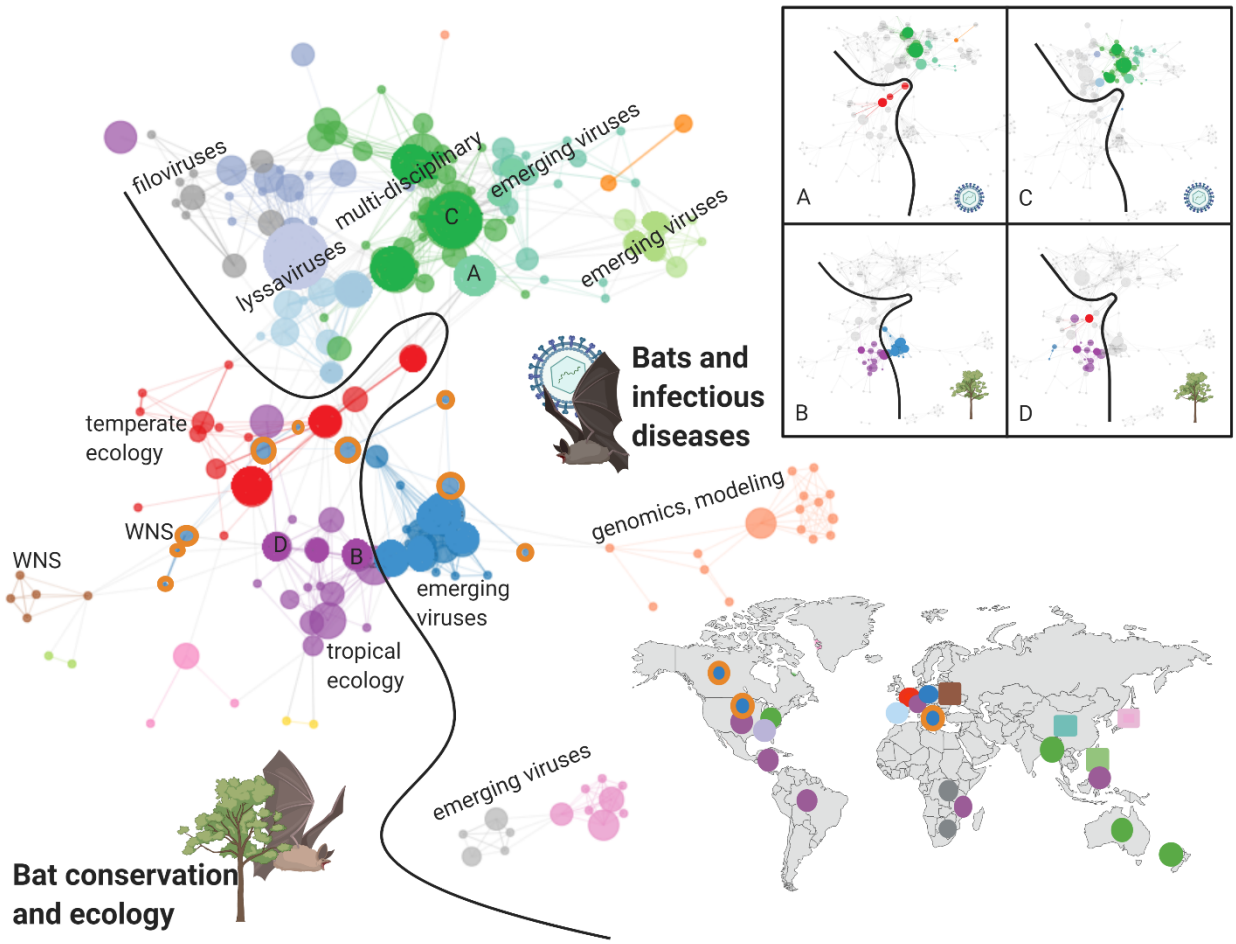

Fig. 1. Co-authorship network of the 200 most published bat researchers between 1950 and 2019. Map shows location of institutional affiliations of authors in each cluster. Colors correspond to the author network clusters; squares denote apparent segregation of research groups geographically in addition to topic area. Inset shows the publication networks of four influential authors with betweenness centrality scores >500. Authors "A" and "B" are boundary-crossing authors with collaboration networks that span clusters in both ecology and disease topic areas. Authors "C" and "D" are widely connected within either the ecology or disease communities, but do not collaborate across disciplines. Clustering was also driven by geographical and institutional boundaries associated with programmatic missions or funding (inset map) promoting homogenous perspectives within the cluster and potentially retarding dissemination of findings. WNS = White Nose Syndrome. See Supplementary Methods for additional detail on this analysis.

Supplementary Methods

From ISI Web of Science (WoS), we extracted papers under the topic “bats” or “chiroptera” from 1950 – 2019. The resulting 28,001 citations were refined to 7,425 by filtering for articles indexed by SCI and SSCI in the WoS categories “ecology”, “multidisciplinary sciences”, “biodiversity conservation”, “virology”, “infectious diseases”, and “immunology”. Unrelated papers were manually removed, reducing the final dataset to 5,645 papers. Records were imported into Bibliometrix (10). We employed co-author analysis to analyze the social structure of the field (1) and build a network map of authors (nodes) linked by co-authorships (Fig 1). Clusters, generated with the Walktrap algorithm, comprised authors who published together significantly more frequently than with others. Primary research themes of clusters were identified from professional experience and inspection of publications. Betweenness centrality scores for each author (range: 0 - 2,250) were calculated (2). Authors with high betweenness centrality connect different parts of the network, either within or across disciplinary boundaries.

Hi Kendra,

Great - thanks so much! I'll send Anna your way. Yes, I agree that EHA may be a great fit for her, and she is thrilled there are open positions! And the Iowa connection. We talk Iowa a lot because my husband's family farms in Iowa....right along I-80 between Omaha and DesMoines, by the yellow smiley face water tower at the Adair/Casey exit...we're headed there next week actually. Small world! I'll definitely loop you in about anything with BOHRN that you could contribute to - I appreciated all your input at the Vienna meeting and it would be great to have you involved. We had a lot of momentum after that meeting but they've been very quiet lately....DTRA seems to be going through some restructuring. But if things calm down by this fall I think they will try to have another meeting and get things going again.

Thanks!
Rebekah

Hi Rebekah,

Great to hear from you, and I hope you are doing well too! I would be happy to chat with Anne about the available positions at EHA, please pass my email to her and we can set up a time to chat. I did a quick search of Anne, and besides being an amazing scientist that I think would be a great fit at EHA, I noticed she completed her undergrad in Iowa (which is also my home state).

In terms of BOHRN initiatives, if I can contribute in any way please feel free to contact me. I often get overlooked with both Jon and Kevin being BOHRN members.

Cheers,
Kendra

On Jun 25, 2020, at 1:54 PM, Kading,Rebekah wrote:

Dear Kendra,

I hope this message finds you hanging in there ok during all of this! Thank you also for all your hard work on this North American bat paper! I've been interacting regularly with Tigga through the IUCN Bat Specialist Group and working on another paper; it's been nice keeping up with her outside of BOHRN. With everything going on with the bat research community and SARS-CoV-2 though, lots of BOHRN members are involved in various initiatives and and keeping pretty busy...someday when we are on the other side of this, I hope DTRA revitalizes a BOHRN meeting in person so we can all reconnect, debrief, and move some ideas forward that we had been discussing. I don't think anyone would accept another Zoom meeting at this point though!

Anyway, I'm writing to ask if I can put you in touch with a DVM/PhD student in my lab, Anna Fagre. Anna is outstanding, and interested in applying for one of the open positions at EcoHealth and just wants to do due diligence in finding out more about the position, expectations, etc. I thought of you as being a good person to provide some inside perspective, but wanted to reach out first to make sure that wouldn't put you in an awkward position, like if you're on the hiring committee or something.

Thanks so much!

Best regards,
Rebekah

Subject: Re: SARS-CoV-2 spillover risk to North American bats manuscript - FINAL version for PLOS Pathogens (new plan)

- External Email -

Hi Team,

Funny thing, bioRxiv actually rejected us! Apparently they don’t take “reviews”.

In any case we got **very positive reviews back from *PLoS Pathogens*** today, and the revised ms was just resubmitted (<24 hour turnaround). Woohooo! Finger’s crossed that the editors turn it around again quickly and we can see this published soon.

Attached is the cover letter, response to reviewers, and the resubmitted version of ms.

Cheers,
Kevin and Paul

Dear all,

We successfully submitted to bioRxiv yesterday and it’s currently in “review” with the editorial staff and should be posted within 48 hours. Big thanks to Paul for getting the final USGS approvals and ms formatting in place.

Hume and Charlie, I understand your very valid and “traditional” concerns here, there’s a lot of riff-raff out there on pre-print servers and hence why we have the peer-review system. Nonetheless, given that there are other similar reviews being posted at the moment and the timeliness of this given the USGS/USFW Risk Assessment out last week, etc., would be best to get this out there while we’re still in review at PLOS.

Best,
Kevin

Dear all,

Update on our ms. It was submitted to PLOS Pathogens on June 2nd (you should have all received an email from the journal confirming this) and it is currently under review.

We are in the final stages of USGS approval to also submit to bioRxiv (pre-print server), and expect to finalize that and post it on bioRxiv in the next 24 hours. *Please let me know if there are any objections.*

Cheers,
Kevin

Hi Folks,

Quick update on our paper — unfortunately got news yesterday that *PNAS* was not interested in this as a Perspectives piece, and rejected our proposal. We are currently pursuing options with editors at *PLOS Pathogens* to see if they want it as a review. Will keep you all posted.

Latest version attached that has cleared CDC and USGS review. We will still aim to get this on BioRxiv, but wanted to wait until we had it cleared first and ideally in review at a journal.

Cheers,
Kevin

On 12 May 2020, at 10:13 PM, Kevin Olival < ecohealthalliance.org> wrote:

Dear Co-authors,

Attached is the latest, submission ready version of our paper "**Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats**". Thank you all for the last round of invaluable edits and comments. Paul and I have now gone through multiple revisions since you last saw the paper in an attempt to include everyone's feedback; so apologize for the delay in turning this around and moving towards submission.

We started a submission to *Lancet Infectious Diseases*, but after thinking more about the journal's scope and reading other recent reviews that have been published in the journal, Paul and I decided it was not the best fit after all. We instead plan to submit this as a Perspectives article to *PNAS*(https://www.pnas.org/page/authors/purpose-scope). We think *PNAS* is a better fit all around, especially given the US focus of our review. We are currently following up some leads for "sponsorship" of our paper with PNAS which would make it an invited piece. If you have any specific suggestions in this regard, please let me know.

As before, the plan is once we submit (hopefully this week) to *PNAS* we will also post as a pre-print on BioRxiv so it can be viewed and used immediately. **If there are any objections to this plan or to submit to *PNAS*, please let me know.**
Also, for those that have secured USG approval already, please let me know if these needs to be updated or if you need any more information.

This has been a fantastic exercise in group writing! Big thank you to everyone.

Cheers,
Kevin

Hi Tigga and everyone,

Yes, that is challenge for me as well. I am not involved in the Georgia meeting, but have made arrangements regarding class coverage so I could travel to Vienna if we proceed with that meeting in Nov. I also would not have been able to get away for both meetings though. January, after the semester is over, is generally better timing for me too. There was a December meeting option as well, which unfortunately for me would fall during the last week of classes so I couldn't get away for that, but if that works better for the majority of the steering committee perhaps we should reconsider it?

Kind regards,
Rebekah

Subject: RE: Draft Executive Summary and Website Materials

Hi Megan
Just trying to unpack the plans this fall, and have been reading through the Exec summary. Essentially a lot of BOHRN are going to Georgia and you propose an additional meeting in Austria a couple of months later?

I don’t want to second guess what you all decided on in Canada, but is there any chance the second meeting (currently scheduled for November) could be when the fall semester is over (i.e. early-mid December through mid January)? As I’m on the WABnet Steering Committee I have committed to the Georgia meeting, but it is challenging to get release for multiple trips during the academic semester, particularly for same entities. I am probably not the only one running into this problem or similar

Thanks for your consideration,
Tigga

Subject: Draft Executive Summary and Website Materials

All,

Please find the draft report from our BOHRN meeting 20-21 June. This report includes an executive summary, action items, participant list, working group outcomes, and your research quad charts.

We ask that you provide constructive comments (e.g., content changes) no later than 18 July. It is our intent to adjudicate and incorporate any comments to then publish a final report.

In addition, you will find an updated version of the website map here (https://docs.google.com/document/d/1x5GdAKEPpKXTol9utZiYvaGoXNtOQsyTdlub1WvN0tk/edit?usp=sharing). Each page has the title of the website page and the content, make edits, as you see fit, to the language to help us better develop the website.

As a reminder, we will be adding individual bios to the website. If you have not already done so, you may submit your information here: https://www.surveymonkey.com/r/BPMTG2T

You will find the report contains softened language to add a more conservationist view point, please review the language within the report and on the website.

v/r,

Megan

Hi Kevin,

Very nice job on this! Only spotted a couple small things.
1) "highlights" is misspelled on line 128.
2) looks like a ref is still needed in line 342 regarding PPE usage in the field. This ref might fit...it's more broadly on wildlife professionals though (PMID: 31993824)
3) don't forget to delete the [...] on line 421

Yes, I would be delighted to be a co-author.

Thanks so much!

Towner
Subject: Final version of North American bat/SARS2 ms - PLEASE REVIEW

Dear Esteemed Colleagues,

Please review the attached penultimate draft of our manuscript (now entitled: **"Possible risks of SARS-CoV-2 spillover to free-ranging wildlife: a case study of bats")**, together with the supplementary table and refs. Our plan is to submit to *Lancet Infectious Diseases* as a review article (correct length and they allow 150 refs) in the next week - references are currently formatted for that journal. We would also like to post it on bioRxiv as a pre-print once we get it submitted to *Lancet ID*. Please let me know if you have any concerns with that plan.

Thank you all for your excellent comments and edits on the previous draft. Paul and I have gone back and forth on several rounds of revisions since then (and multiple late night texts), aiming to take each and every suggestion into account, and we believe it's a much better manuscript now! Very excited about this one, and looking forward to getting it published!

By Thursday April 30th (or ASAP), could you each please:

1. Confirm that you agree to be a co-author.
2. Double check your name and affiliation, and send me your ORCID number if you have one.
3. Read through the ms and send any important, last minute changes or edits you feel are necessary. Please use track changes. If you're okay with the ms as is, please just confirm so.
4. For my Federal US Gov't friends (USFWS, USGS, CDC, USDA) - please let us know what we need to do for approval on your end. I know Paul is working with USGS now to hopefully get rapid clearance.

No need to cc all if you don't want, but please include both me and Paul on your response.

Looking forward to hearing from you all soon!

Cheers,
Kevin and Paul

Subject: Re: Preventing human-to-bat transmission of SARS-CoV-2 Figure

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Subject: Re: Preventing human-to-bat transmission of SARS-CoV-2 Figure

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Dear Tigga,
I just wanted to let you know that I've sent this to 2 email addresses for Rodrigo and it seems they have bounced back. I am not sure if he has seen my request.

I hope to hear from you soon about whether the Wildlife Health Specialist Group can use or modify your infographic (with the appropriate credit).

Best,
Mindy

Preventing transmission of SARS-CoV-2 from humans to wild mammals

Exposure Risks

Contact exposure
Mammals coming into contact with contaminated hands or equipment

Aerosol exposure
Infectious droplets from handlers holding mammals in close proximity

Environmental exposure
Sharing enclosed, poorly-ventilated spaces with mammals, where virus may persist in the air or on surfaces

MAP your plan to prevent transmission to mammals!

Mitigation Strategies

Minimize

Delay, prioritize, or avoid handling mammals when possible, i.e. collect environmental samples

Assess

Postpone handling mammals if there is a probability that you have been exposed to SARS-CoV-2 or if you have symptoms

Protect

Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures

This figure was adapted in collaboration with the IUCN Bat Specialist group.

Preventing transmission of SARS-CoV-2 from humans to wild mammals

Hi Mindy,

Thanks - I'm so glad you like it! I'll await to hear about any final edits the group might want to see. I'll also defer to Tigga and Rodrigo for how they'd like to handle the branding on this infographic. I do think the infographic alignment between the working groups is pretty cool, and will be good for consistency in messaging.

Kind regards,
Rebekah

Dear Rebekah,

This looks awesome!! I shared it this evening with our small team that is preparing the guidelines for the rest of the specialist group to review and they like it very much (that's a great ferret:)! We are going to share the guidelines tomorrow with a larger team in the specialist group for the final review so this is perfect timing.

I will also find out about branding from the WHSG and will get back to you on that. I also want to make sure we also give credit your specialist group. Tigga and Rodrigo, as I mentioned we will include a statement that this is modified from the BSG's figure. Please advise on any other branding requirements.

Thanks very much!!

Kind regards,

Mindy

Hi Kendra -

Thank you! I'm glad you like it! I have a subscription to BioRender for my lab...well worth the investment...so we get unlimited images, don't have the watermark on it, and can export high resolution for use in publications, grants, presentations etc. I started playing around with the free version though just to be sure I liked it, and its been a huge hit with my lab!

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change “bats” to either “mammals” or “wild mammals”, change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from “i.e. implement acoustic surveys” to “i.e. collect environmental samples”, and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn’t need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Attachment(s): "IUCN BSG MAP TRANSLATION SHEET.docx","IUCN infographic wildlife version_cc.pdf"

Hi Billy,

The pdf version should be editable, so they should be able to work directly on that and then re-save as an image file. As an alternative, if anyone in your working group or OIE has a BioRender license, I can share the infographic file directly with that person through BioRender to edit. Third option - I'm attaching a translation sheet that could be used as a template. It still has the bat infographic language on it, but if this is updated with the French and Spanish translations for the wildlife infographic, feel free to send those translations back to me and I'd be happy to update the infographic.

Hope that helps, and just let me know how you'd like to proceed.

Hi Rebekah and all.

Thanks again for the graphic.

OIE is distributing our joint WHSG/OIE guidelines and also translating it to French and Spanish as they normally do. They would like to change the language in the graphic also but need either the editable file or at least the background images on which they can overlay the French and Spanish. Are either of those something you could provide?

Thanks,

Billy

Hi Mindy, Billy, Kevin, and Kendra -

I hope your week has gotten off to a good start!

I'm attaching a draft infographic for your review. I've modified the current BSG MAP infographic per your suggestions for a wildlife version. I can also add a logo, QR, and/or website at the bottom if you'd like. Not sure of exactly the best way to portray environmental samples...I was assuming this will comprise activities like passive fecal sample collections...so please let me know if this captures what you had in mind or if there is something else you're envisioning and I can revise accordingly! (BioRender does have an amusing variety of poo icons, but I was trying to keep it classy and professional.) ��

Take care, and I'll look forward to your feedback.

<IUCN infographic wildlife version_cc.pdf><IUCN infographic wildlife version_cc.png>

Translation Sheet. Please translate the English to your language as closely as possibly and use the same format for the section. If you can retain the “MAP” – Minimize, Assess, Protect that is ideal, but it of course depends on the translation.
Example

Section	**English**	
Title	**Preventing human-to-bat transmission of SARS-CoV-2**	
Tagline	MAP your plan to prevent transmission to bats	
Heading 1	**Exposure Risk**	
Heading 2	*Contact exposure*	
	Bats coming into contact with contaminated hands or equipments	
Heading 2	*Aerosol exposure*	
	Infectious droplets from handler holding bats in close proximity	
Heading 2	*Environmental exposure*	
	Sharing enclosed, poorly ventilated spaces with bats, where virus may persist in the air or on surface	
Heading 1	**Mitigation strategies**	
Heading 2	*Minimize*	
	Delay, prioritize, or avoid handling bats when possible, i.e. implement acoustic surveys	
Heading 2	*Assess*	
	Postpone handling bats if there is probability that you have been exposed to SARS-CoV-2 or if you have to symptoms	
Heading 2	*Protect*	
	Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures	

EXAMPLE

Section	English	LANGUAGE
Title	**Preventing human-to-bat transmission of SARS-CoV-2**	**Cegah Penularan SARS-CoV-2 dari manusia-ke-kelelawar**
Tagline	MAP your plan to prevent transmission to bats	**KENAL**[1] dan rencanakan pencegahan penularan ke kelelawar [1]KENAL: Kurangi, Nilai dan Lindungi Note: Kenal in Indonesia means know, be familiar
Heading 1	**Exposure Risk**	**Risiko Paparan**
Heading 2	*Contact exposure*	*Paparan kontak*
	Bats coming into contact with contaminated hands or equipments	Kelelawar kontak langsung dengan tangan atau peralatan yang terkontaminasi
Heading 2	*Aerosol exposure*	*Paparan aerosol*
	Infectious droplets from handler holding bats in close proximity	Droplet infeksius dari pemegang kelelawar dalam jarak dekat
Heading 2	*Environmental exposure*	*Paparan lingkungan*
	Sharing enclosed, poorly ventilated spaces with bats, where virus may persist in the air or on surface	Berada satu tempat dengan kelelawar di ruang tertutup, dan minim ventilasi dimana virus dapat bertahan di udara atau di permukaan benda
Heading 1	**Mitigation strategies**	**Strategi mitigasi**
Heading 2	*Minimize*	*Kurangi*
	Delay, prioritize, or avoid handling bats when possible, i.e. implement acoustic surveys	Menunda, memprioritaskan, atau sebisa mungkin hindari memegang kelelawar, misalnya menerapkan survei akustik

Heading 2	*Assess*	*Nilai*
	Postpone handling bats if there is probability that you have been exposed to SARS-CoV-2 or if you have to symptoms	Tidak memegang kelelawar jika anda merasa ada kemungkinan terinfeksi SARS-CoV-2 atau memiliki gejala
Heading 2	*Protect*	*Lindungi*
	Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures	Lakukan tindakan yang dapat mengurangi paparan, seperti menggunakan pelindung wajah, masker, sarung tangan, dan langkah desinfeksi

Preventing transmission of SARS-CoV-2 from humans to wild mammals

Exposure Risks

Contact exposure
Mammals coming into contact with contaminated hands or equipment

Aerosol exposure
Infectious droplets from handlers holding mammals in close proximity

Environmental exposure
Sharing enclosed, poorly-ventilated spaces with mammals, where virus may persist in the air or on surfaces

MAP your plan to prevent transmission to mammals!

Mitigation Strategies

Minimize

Delay, prioritize, or avoid handling mammals when possible, i.e. collect environmental samples

Assess

Postpone handling mammals if there is a probability that you have been exposed to SARS-CoV-2 or if you have symptoms

Protect

Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures

This figure was adapted in collaboration with the IUCN Bat Specialist group.

Subject: Reference for Anna Fagre for EID-Search Research Scientist & Project Manager at EcoHealth Alliance

Dear Dr. Kading,

We just interviewed Anna Fagre for a position here at EcoHealth Alliance as a Research Scientist and Project Manager. Our hiring committee thought she was terrific with the right background and attitude for our team. Anna listed you as a reference. If you would be willing to send some comments about Anna, that would be terrific!

I have attached our position advertisement, so you may know more about the position - though based on her skillset, the specifics would evolve a bit. This position would focus primarily on our emerging infectious disease projects based in Southeast Asia including our recently awarded, NIAID funded EID-SEARCH program:

- https://www.ecohealthalliance.org/program/south-east-asia-research-collaboration-hub

I look forward to your reply and should a phone call be more convenient, we could do that as well.

On behalf of our whole committee, I sincerely appreciate your time.

-Aleksei

Subject: Re: Reference for Anna Fagre for EID-Search Research Scientist & Project Manager at EcoHealth Alliance

Dear Aleksei, Peter, and Hongying,

I enthusiastically recommend Dr. Anna Fagre for the Research Scientist and Project Manager position at EcoHealth Alliance.

To speak to Anna's **research experience and capability**: I've known Anna since I joined the CSU faculty in 2016, when she arranged to a rotation as part of her microbiology residency. Anna formally joined my laboratory as a PhD student in July 2017. Her dissertation is focused on the role of bats as reservoirs of emerging arboviruses, and she has made significant progress on both *in vitro* and *in vivo* studies involving bat-associated orbiviruses. The primary emphasis of these studies is on characterization of Bukakata orbivirus, a novel virus that I isolated from a fruit bat in Uganda in 2013. Bukakata orbivirus is putatively tick-borne, based on the phylogenetic analyses we have conducted. To study this virus in the broader context of other orbiviruses that have been isolated from naturally-infected bats, we acquired all three of the remaining bat-associated orbiviruses from the CDC reference collection as well as Chobar Gorge virus, a tick-borne orbivirus to which Bukakata appears to be closely related. Anna's molecular and phylogenetic characterization of Bukakata and other bat-associated orbiviruses was published in a special collection on bat viruses, in the journal Viruses (PMID: 30832334) along with a comprehensive review of the potential for bats to serve as reservoirs for arboviruses (PMID: 30832426). Since the time these papers were completed, Anna has also put significant effort into investigating the use of subgenomic RNA derived from the 3'UTR of flaviviruses to look for evidence of past infection in archived tissue samples. Because of the complex hairpin structure of the viral RNA in the 3'UTR, it is protected from RNA degradation by the exonuclease XRN1, so we hypothesized that we would find residual viral RNA that could be amplified and sequenced. After optimizing this methodology, Anna screened all of our remaining bat tissue samples from Uganda, going back 10 years, and discovered that 4 bats between 2009 – 2013 had been infected with Zika virus. Moreover, this Zika virus sequence was most similar to the Asian lineage, suggesting either diversification of Zika virus strains prior to the virus expanding into Asian in the ~1960s or spillback into Africa of the epidemic strain much earlier than we have appreciated. This manuscript is currently in review. All in all, Anna's work in my lab has been top-notch. She is meticulous and hard-working and has an excellent grasp of the molecular methodologies and big picture of how they can be applied innovatively in an ecological context. In each of these projects, she has done an excellent job leading, and taken initiatives beyond the original study scope that have made the work much stronger in the end. Her **background in veterinary medicine** has also added valuable perspective, and been very much in-demand as she has helped other laboratories on campus during this pandemic with *in vivo* studies involving SARS-CoV-2.

Other key attributes relevant to the current opportunity:

Anna is highly **collaborative,** personable, and very proactive in seeking these collaborations. This year she has re-connected with a former CSU graduate school colleague who is now in Bangladesh, and has been actively developing some research ideas and using her own funding to generate preliminary data. She also joined the VERENA consortium and has been working on a review paper with collaborators in that group. She works very well with others, as a leader of diverse teams as well as a contributing member. She has had the opportunity to contribute to a number of **international projects** both as part of my lab and during her previous experience, and is very adaptable, capable, and enthusiastic about working internationally. Over the past year she has been an invaluable member of an global initiative led by the CSU Office of the Vice President for Research, and has earned the respect of the highest CSU leadership for her contributions to this team.

Anna has been successful at **securing extramural funding**, of her own initiative. Since joining my lab, she has been awarded three highly-competitive fellowships and grants: An NIH TL1 fellowship through the Colorado Clinical and Translational Science Institute, a spot on the NIH T32 award to CSU, and the 2019 Robert E. Shope International Fellowship in Infectious Diseases through ASTMH/ACAV.

Anna is an excellent writer and **science communicator**, and also publishes frequently on blogs and other social media platforms in addition to her prolific peer-reviewed publications. She is the literature watchdog of the lab, and somehow seems to know about every relevant paper or report that is published within a half hour of it hitting the press. Anna has excellent soft skills when interacting with other professionals. She was featured in a documentary video made by CSU, and had a very natural presence and ability to clearly explain her research and general principles of disease ecology in lay terms.

In conclusion, I give Anna my highest recommendation and think she would be a fantastic addition to your team. Anna is extremely proactive, self-motivated, skilled, and has brought a wonderful energy and work ethic to my laboratory. She is an up-and-coming leader in the field, and I am thrilled to have her as part of my team. This turned out to be not-so-brief a recommendation, but I hope was a useful assessment! If you have any questions or if I can be of any additional assistance, please do not hesitate to contact me.

Best regards,
Rebekah

Dear Dr. Kading,

We just interviewed Anna Fagre for a position here at EcoHealth Alliance as a Research Scientist and Project Manager. Our hiring committee thought she was terrific with the right background and attitude for our team. Anna listed you as a reference. If you would be willing to send some comments about Anna, that would be terrific!

I have attached our position advertisement, so you may know more about the position - though based on her skillset, the specifics would evolve a bit. This position would focus primarily on our emerging infectious disease projects based in Southeast Asia including our recently awarded, NIAID funded EID-SEARCH program:

- https://www.ecohealthalliance.org/program/south-east-asia-research-collaboration-hub

I look forward to your reply and should a phone call be more convenient, we could do that as well.

On behalf of our whole committee, I sincerely appreciate your time.

Subject: RE: SARS-CoV-2 spillback risk to North American bats

Hi Paul
Very interested to see the MS. Rebekah and I have been working on something that arose out of BOHRN that would be very complementary and might be worth trying to coordinate dissemination in some way. We are meeting today and will take stock of where we are at.

I just started an email to you and Kevin about the state of affairs as we Rodrigo and I are getting quite a bit of push-back on the IUCN BSG recommendation to suspend field studies while further data are gathered (primarily from western scientists with access to PPE). It would be good to hear what those committees are finding sooner rather than later.

Best wishes
Tigga

Subject: SARS-CoV-2 spillback risk to North American bats

Hi Tigga,

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of

disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Greetings everyone! Thank you for the update - I will stay tuned to see how the situation unfolds. I am available on those dates should that work out. We could try a Zoom meeting sometime in the interim, if that would be helpful to get everyone "together"? I know many BOHRN members have been collaborating and contributing to the pandemic response in a variety of ways, which I think represents some successful grassroots mobilization of the network. Might be encouraging to have something of a group call to hear about what folks have been up to and if there's anything we can band together more formally to accomplish despite being scattered. Just an idea to throw out there!
Kind regards,
Rebekah

Dear BOHRN TRN Steering Committee Members,

We hope you have been able to remain safe during these times and that this email finds you well. As you may already know, the World One Health Congress has been rescheduled to take place on October 30 - November 3 in response to worldwide travel restrictions and to coincide with International One Health Day on November 3rd. We wanted to inform you that the BTRP TRN side meetings have been rescheduled in tandem with the Congress, now aiming to take place on November 3 - 4. This is a change we are trying to implement, however, we understand the current scope of world events and anticipate further changes as we go forward. Our utmost priority is everyone's safety and we will continue to monitor the situation to act accordingly. We will be sure to keep you informed of all updates.

Please let us know if you have any questions and stay safe.

Kind Regards,

GSE Logistics Team

Subject: World One Health Congress and BTRP TRN Side Meeting - BOHRN

Dear BOHRN TRN Steering Committee Members,

On behalf of Dr. Martha Stokes, please accept this Save the Date to attend the World One Health Congress in Edinburgh, Scotland 15-17 June 2020 and participate in side meetings on BTRP's Threat Reduction Networks and planning for BOHRN.

Tentatively, we plan to hold two sessions at the end of the week: Thursday, 18 June - an afternoon TRN session that will include a wide group of BTRP-funded participants from its other research networks to discuss network metrics for sustainability; Friday, 19 June - a side meeting for BOHRN to map out its schedule and strategy, aligning with funding opportunities from BTRP and other entities. Attached is a tentative schedule for the week, for your reference. Due to travel and budgetary constraints we are unable to invite the entire steering committee, but intend to have productive discussions and meet objectives with the smaller group on this Save the Date email.

Please let us know if you will be able to attend the WOHC and side meetings on 18-19 June. Official invitation with travel instructions, details on arrangements, and more formal agenda will be forthcoming. Please note that there is a potential for the WOHC and BTRP side meetings to be postponed, given the current travel uncertainties related to COVID-19. We will be monitoring the status of the conference, and will keep you apprised of any cancellations should they occur. As always, let us know if you have any questions!

We hope to see you in Edinburgh!!

Subject: Re: World One Health Congress and BTRP TRN Side Meeting - BOHRN

Dear Caitlin, and hello everyone,

Thank you very much for the invitation! I would very much like to attend and participate in these discussions regarding BOHRN, but I have a couple of complications. Colorado State University currently has a restriction on international travel until further notice, but it's hard to know what things will be like in June. Hopefully that would be lifted by then. These dates also overlap with the Infectious Diseases of Bats Symposium being held at CSU June 17-19 after the American Society for Virology meeting, and I confirmed awhile ago I would participate in the bat meeting here. I think I should honor that existing commitment, which means I will not be able to attend the BOHRN steering committee meeting in Edinburgh. If this affects more steering committee members than just me, would having the BOHRN meeting in conjuction with the bat ID be a possibility? I understand if not, and I will look forward to catching up with everyone at the next opportunity!

Best regards,
Rebekah

Dear Marty, Katie, Megan, Jon, and Tigga -

I just wanted to send a quick message to thank you for all your hard work on our BOHRN meeting last week! I know that took an amazing amount of coordination to get so many more people there, and I thought it was a very productive time! It was nice to have formal talks from some folks, and the white paper exercise was a great way to get people working together. I appreciate all the time and energy you each put into BOHRN -- it is a unique group with an important purpose and I am excited about the trajectory we are on so far! I'll look forward to touching base again soon about planning the Uganda meeting in the spring.

Take care and have a great week -

Subject: Reception at U.S. Embassy (Context)

All,

You likely received an invitation from “Protocol Bangkok” inviting you to a Prince Mahidol Award Reception at the U.S. Ambassador’s residence on Thursday, February 1 from 1800 – 2000.

Here is a bit of context about the event: this year, the United States became the first country to receive awards in all categories of the Prince Mahidol Awards, which are awarded annually under patronage of the Thai Royal Family to individuals and organizations that have made outstanding contributions to medicine and public health. Historically, winners have been forerunners to Nobel prizes. This year’s American awardees include the Human Genome Project and a team of researchers who developed a vaccine against Haemophilus influenza.

The U.S. Ambassador is not only proud of this historic American accomplishment, but would also like to use the opportunity to highlight the U.S. Government’s long history of military and civilian cooperation on health issues in Thailand and the greater region. The 60-year history of U.S. – Thai health cooperation is one of the lesser told success stories of the long-standing relationship with a close regional ally; and further, an alignment with the 200-year anniversary of U.S. – Thai friendship, which also occurs in 2018.

CBEP is very much a contributor to U.S.-Thai military and civilian cooperation and accomplishment on health issues; therefore, Dr. Stokes and her colleagues are co-sponsoring the celebration at the Ambassador’s residence and provided your names as their guests to the event. On behalf of her and the CBEP delegation, we very much hope you will attend.

Please let me know **if you did not receive an invitation**. Please also let me know if you have any questions. Otherwise, please follow the instructions in your invitation for favorable response.

Thank you!

Subject: Bat Facility meeting
Location: Microsoft Teams Meeting

Start: Tuesday, March 31, 2020 12:00 PM EDT
End: Tuesday, March 31, 2020 1:00 PM EDT
Show Time As: Tentative

Recurrence: None

Meeting Status: Not yet responded

Organizer: Kendall,Lon
Required Attendees: Kendall,Lon ; Angela Bosco-Lauth >; Bowen,Richard ; Dean,Gregg ; epstein ecohealthalliance.org>; Schountz,Tony >; Szalai,Edit >; bpope jean.patterson >; mchallberg < ; Ebel,Greg >; Cassetti, Cristina (NIH/NIAID) [E]

Here is tomorrow's agenda. Talk to you all tomorrow. You should be able to join by clicking the link below.
Introduction
Lon- why meeting was initially organized, then turf to Jon (I won't be long)
Jon- provide background about program discussions with CSU and NIAID and why we are here (Jon really sparked this discussion, and is probably best to lead)
Jean- Discuss NIAID possibilities and expectations and what's needed from CSU (Thought Jean should go sooner to help frame discussion below. I will send her agenda once we get it finalized)
Ebel- Discuss CVID abilities, and possibilities related to emerging disease, prior C06
Tony- Discuss current research and potential needs
Bowen/Angela- Discuss current research and potential needs
Determine next steps

Subject: Genome paper

Jon, I suspect you've seen this?

https://www.frontiersin.org/articles/10.3389/fmicb.2020.01807/full

Should be quite helpful for the grant.

Subject: Monoclonal antibodies

Jon, I think a really important part of the grant will be to make monoclonal antibodies to various proteins (e.g., CD antigens, cytokines) and cytokines as reagents. If you agree, I'd like to approach a colleague of my, Brian Geiss, to see if he is willing to be on the grant. Recombinant protein expression is his "thing" and he would be a great asset for the grant.

I also think we should get as many letters of support that we can get. I can probably get at least 10 from people we've helped over the years (provided tissues and cells, conducted experimental infections, etc.).

Let me know what you think.

Just moved into our new building. It is really sweet. :)

Thanks,

T.

Yes, I'd like to start on it next week. I have some grading to do this week plus interviews for DVM/PhD candidates for our program, so calendar is quite full. Next week is pretty good for me except (MST) Monday 2-3, Tues 12-2, Wed 3-5. Any of those work for you?

Thanks,

Tony

It would be a great idea to have another building in-country for housing and staging bats for quarantine before shipping to USA.

Getting on a call with DARPA in a few minutes, so won't be responsive for an hour or so.

Awesome - and agree.
I would like to brainstorm together for the letters before we approach anyone. I'll start a google doc and we can live edit it.
Let's think about who the 'dream team' will be for this.
It also occurred to me - what do you think about building in a facility in Bangladesh where we keep a captive breeding colony, that would serve as a feeder if we need more bats along the way? We could develop and fund a closed colony there, like what Cambridge did in Ghana, and we'd know the status of each bat. Brian Pope would be great at helping set this up. And it would allow the colony at CSU to fluctuate a bit in size, and we could pull in new bats as needed. I think it's a nice insurance policy to support the colony in CO as we develop it. This could be something I would manage - but I think we could convince the govt and if we provide all the funding for construction and upkeep, it could really happen.

Thoughts?

On Oct 7, 2020, at 1:51 PM, Woodson, Sara (NIH/NIAID) [E] wrote:

Hi Tony, Jon, and Greg;
Here are the example R24's you may want to look up in NIH Reporter:

R24AI059830 PI: Jacques Robert (University of Rochester, animal model containing)
R24AI120942 PI: Scott Weaver (University of Texas Medical Branch, WRCEVA—no model development but may be relevant if thinking about including training; may also be good to link in with them for potential distribution of critical reagents along with BEI Resources)

As Mark mentioned on the phone, NIAID doesn't allow a lot of R24 grants and thus not many are funded, so there aren't many relevant examples to what you would be putting forth in your R24. Please let me know if you have other questions or concerns!
Happy writing 😊
Sincerely, Sara

Dear Ben,

Your abstract submission has been accepted for a **POSTER** presentation. The session is **Friday, April 30 from 12:00 to 2:00 PM** in the University Center for the Arts. The maximum size of your poster **should not exceed 122 cm/48 inches height and width**. We will provide push pins for mounting your poster on the easel. If you have questions, please feel free to contact me.

Thank you and we look forward to your presentation.

Dear Tony,

Thank you for your organizing the nice bat ID symposium. We enjoy very much th discussion with the scientists of different speciality.

Thank you for your considering to participate in the meeting "8th International symposium on emerging viral dieases" to be held in Wuhan in Ocotber, 2018. We will add you at the email distribution list and let you know as soon as we have a fixed date. Usually, the meeting will be held at the 4th week with the duration of 3 days (with 2 days of scientifc activity).

Looking forward to meeting you again,

Best regards,
Zhengli,

Hi Zhengli,

I hope your travel home was peaceful. I wanted to thank you for your attendance and presentation at the bat ID symposium. I think it was a very good meeting and I hope others benefited from it. We are already planning to host it again in 2020.

If you have an email distribution list for the conference you're hosting next year, could you please add me to it? It looks like a great meeting and if I can get travel arranged I would like to come.

Thank you,

Tony

Subject: Bat Facility meeting
Location: Microsoft Teams Meeting

Start: Tuesday, March 31, 2020 12:00 PM EDT
End: Tuesday, March 31, 2020 1:00 PM EDT
Show Time As: Busy

Recurrence: None

Meeting Status: Not yet responded

Organizer: Kendall,Lon
Required Attendees: Kendall,Lon >; Angela Bosco-Lauth < >; Bowen,Richard < ; Dean,Gregg ; epstein ecohealthalliance.org>; Schountz,Tony >; Szalai,Edit bpope < >; jean.patterson ; mchallberg >; Ebel,Greg >; Cassetti, Cristina (NIH/NIAID) [E]

Here is tomorrow's agenda. Talk to you all tomorrow. You should be able to join by clicking the link below.
Introduction
Lon- why meeting was initially organized, then turf to Jon (I won't be long)
Jon- provide background about program discussions with CSU and NIAID and why we are here (Jon really sparked this discussion, and is probably best to lead)
Jean- Discuss NIAID possibilities and expectations and what's needed from CSU (Thought Jean should go sooner to help frame discussion below. I will send her agenda once we get it finalized)
Ebel- Discuss CVID abilities, and possibilities related to emerging disease, prior C06
Tony- Discuss current research and potential needs
Bowen/Angela- Discuss current research and potential needs
Determine next steps

Subject: Action needed: check your proof 10.1093/infdis/jiz648

Dear Dr. Vincent Munster,

You must check your proof now to avoid delaying publication.

What you need to do now:

1. Access your proof https://pubkit.newgen.co/auth_token_login/af89fcf9-b35f-40b5-a782-420952f1a4a4

2. Respond on the proof to any copyeditor queries.

3. Approve your proof for publication or submit minor formatting corrections within one working day.

Please note that this is causing a delay to the publication of your manuscript. Please contact us if you need any help.

Best wishes,

The Journal of Infectious Diseases production team

Subject: Agenda of the 8th International Symposium of Emerging Viral Diseases
Attachment(s): "Program of the 8th ISEVD.pdf"

Dear speaker:

We have made the program for our emerging virus symposium. Your presentation is scheduled in the afternoon of 21st October, in the session "emerging viral pathogens".

I have attached the program for your information.

We have reserved accommodation for you at the conference venue, Optic Valley Plaza hotel. Please provide me your flight information once it is available, and we will arrange pick-up service at the airport.

Also, please send me your update CV by 7th October, as we would like to include the CV of our speakers together with the abstracts in the conference proceedings.

Thank you!

Best wishes

Ben Hu Ph.D

Wuhan Institute of Virology, CAS
Secretary of the 8th ISEVD

Program of
The 8th International Symposium on Emerging Viral Diseases

Date 日期	Time 时间	Content 议程
Saturday 星期六 Oct. 20, 2018 10 月 20 日	**Venue 地点** 09:00-21:00	**Registration**/报到注册 Ground Floor, Optics Valley Kingdom Plaza Hotel/光谷金盾大酒店一楼大厅
Sunday 星期日 Oct. 21, 2018 10 月 21 日	**Day 1, Morning Session /第一天上午**	
	Venue 地点	Banquet Hall of Optics Valley Kingdom Plaza 3nd floor of the hotel 光谷金盾大酒店三楼宴会厅
	08:30-08:40	**Opening Address/开幕式致词**
	08:40-11:50	**Session 1: Antiviral Immunity** **Session Chairs: Peng ZHOU, Linfa WANG**
	08:40-09:10 Keynote Speech S-01	**Title:** Holy immune balance, batman! **Speaker: Linfa Wang** Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore
	09:10-09:30 S-02	**Title: To be determined** **Speaker: Yanyi Wang** Wuhan Institute of Virology, Chinese Academy of Sciences
	09:30-09:50	Group Photo of Symposium Participants/与会代表合影 Coffee Break /茶歇
	09:50-10:10 S-03	**Title:** Recent advances in developing therapeutics monoclonal antibodies Against Ebola Virus Infection **Speaker: Xiangguo Qiu** Special Pathogens Program, National Microbiology laboratory, Public Health Agency of Canada
	10:10-10:30 S-04	**Title:** Nipah virus and Hendra Virus: Basic Science to Global Countermeasures **Speaker: Christopher Broder** Department of Microbiology, Uniformed Services University, Bethesda, MD, USA
	10:30-10:50 S-05	**Title:** Immunopathogenesis of Nipah virus infection **Speaker: Branka Horvat** International Center for Infectiology Research - CIRI, INSERM U1111, University Lyon 1, France
	10:50-11:10 S-06	**Title:** Incorporation of NS1 and PrM/M confer more effective protection for ZIKA virus vaccine **Speaker: Ling Chen** Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou, China

11:10-11:30 S-07	**Title:** Antiviral RNAi immunity – from basic to translation **Speaker: Xi Zhou** Wuhan Institute of Virology, Chinese Academy of Sciences
11:30-11:50 S-08	**Title:** To be determined **Speaker: Shi Liu** Wuhan University, China
11:50-12:05 Sponsor Presentation	Newly Technology development of Cryo TEM by JEOL **By Jianzhong Yuan** TEM product manager of JEOL in China
12:05-14:00	Lunch/午餐
Day 1, Afternoon Session /第一天下午	
14:00-17:30	**Session 2: Emerging viral pathogens** **Session Chairs: Zhengli SHI, Peter DASZAK**
14:00-:14:30 Keynote Speech S-09	**Title:** To be determined **Speaker: Hualan Chen** Harbin Veterinary Research Institute, Chinese Academy of Agricultural Sciences, Harbin, China
14:30-14:50 S-10	**Title:** Forecasting future viral pandemics and the Global Virome Project **Speaker: Peter Daszak** EcoHealth Alliance, New York, USA
14:50-15:10 S-11	**Title:** Infection and Immune Responses of Jamaican Fruit Bats (*Artibeus jamaicensis)* Experimentally Challenged with a Bat HL18NL11 Influenza A Virus **Speaker: Tony Schountz** Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University
15:10-15:30 S-12	**Title:** To be determined **Speaker: Di Liu** Wuhan Institute of Virology, Chinese Academy of Sciences

Subject: ASCB/EMBO Online Meeting

Dear All,

I would like you to consider submitting abstracts to the 2020 ASCB/EMBO Meeting, which will go virtual.
https://www.ascb.org/cellbiovirtual2020/program/

I will be co-chairing a mini-symposium in the scientific track, Cells in Distress and Disease

My initial proposal focused on host-pathogen interactions at a molecular level.

We are currently accepting abstracts for consideration to give a talk in the 2020 Minisymposia.

The deadline for submission is July 30.
https://www.ascb.org/cellbiovirtual2020/abstracts

PLEASE SHARE THIS INFORMATION WITH OTHER COLLEAGUES WHO MAY BE INTERESTED. THANKS

All the best, Roberto

Subject: Bat Challenge

Hi Tony,

Sorry for late notice, but I didn't want to promise something this time without following through, so Simon (Anthony) can actually vouch for me.

STRICTLY CONFIDENTIAL-For your eyes (and ears) ONLY.
If you are free tomorrow at about 4 pm EST, can you Skype or Zoom in (I'm sure Jon Epstein can figure something out). I'm presenting data to relevant company at EcoHealth Alliance.

Anything bat-related is, of course, hot right now. So, this time, if you agree to help, yours will be the last experiment, not the first.

Meanwhile, if you get this message in time, can you let us know (Simon and Jon is CC-ed on this email) what species of bat you have in your colony? It's important for us to check something before hand.

Thanks! (Again, I apologize for the short notice, what's left of my life has been consumed by my second full-time job on Twitter)

Best regards,

Benhur

Subject: Bat housing

All,

Alan asked me to follow up on the renovations of the bull barn for bat holding. I did a quick space assessment of the building. It is approximately 2500 sf, including a 100 sf storage area. I am assuming of the 2500 sf we'll need about 500 sf for storage, feed prep and procedure space. The AZA recommendations for Pteropus giganteus is 15'x30' per 6 bats. With 2000 sf, that leave us holding for 24-29 bats. If there are some other housing guidelines someone has, please let me know.

On the call we discussed 40-60 bats. I'm looking for advice on how to proceed. We can look at extending the footprint to accommodate 40-60, but I'm not sure what the program needs will be.

Thanks,

Lon

Subject: Bat ID Symposium logistics
Attachment(s): "Campus map.pdf"

Dear Colleagues,

The symposium is one week away and I want to provide you with some logistical information for your arrival to Fort Collins.

1. Speakers. If you can email your presentation directly to me I will get it on the computer for the presentation**However, the file size must be less than 15 MB to accommodate our email server limit**. Otherwise, please bring your presentation on a USB drive if it is larger than 15 mb. We will have both Microsoft Power Point and Apple Keynote software for your presentations. **Bring your USB drive to the Thursday evening reception if you want to transfer it then.**

2. Poster presenters. The maximum size of the posters is 48” x 48” (120 cm x 120 cm). We will provide push pins to mount your poster on the easels. When you register, your poster will have a number assigned to it that corresponds to the easel number. Please mount your poster on that easel. **Bring your poster to the Thursday evening reception.**

3. Getting to Fort Collins. Those of you who are flying to Denver International Airport can schedule a ride with the **Green Ride Airport Shuttle** service. Please visit its web site (https://greenrideco.hudsonltd.net/) to make arrangements convenient for your flight schedules. There is a Green Ride desk in the main terminal at the airport with employees that can help you find the bus pickup. The bus ride is about 1 hour and 15 minutes. On the web site, in the box “Dropoff location” choose the appropriate destination from the pull-down menu. For those of you staying in the university dormitories it is “FC - Laurel Village”, the Hilton Hotel near campus is “FC - Hilton Ft Collins”, and the University Inn is “FC - Best Western University Inn”. And just to make you aware, afternoon and evening flights into Denver can be rather bumpy!

4. Weather and Climate. Fort Collins has lots of sunshine and is at 5000 ft/1500 meters. If you intend to be outdoors much you should bring sunscreen. We often get afternoon thunder showers in our otherwise dry climate but they are typically not more than an hour or two and it usually clears up afterwards. You may want to bring rain gear or a small umbrella. The current forecast is for the mid to high 80sF/low 30sC.

5. Getting to the UCA. The conference venue is the **University Center for the Arts (UCA)** (attached map, blue box, lower right). Oral and poster presentations will be in this building and directions will be posted inside. After you get settled in Thursday, please come to the UCA for the opening registration and social mixer by 5:30 PM. Walking paths (routes) are noted in blue hatched lines.

A. Laurel Village Alpine Dormitory. Those who are staying in campus housing, walk south to Plum Street and turn east to Meridian Avenue. Take Meridian Avenue south to Pitkin Street and take it east to Mason Street. Cross the railroad tracks and immediately turn right (south) just before the parking garage. Follow the path to just past the parking garage and turn left (east). This path leads to a **tunnel that passes under College Avenue** and comes out at the University Test Gardens (lots of flowers). Continue on this path and it will cross Remington Street to the UCA. **Allow 15-20 minutes to walk**.

B. Hilton Hotel. Proceed from the hotel to Prospect and Centre Avenue at the northwest corner of the Hilton Hotel parking lot. Cross Centre to the west and **take the tunnel under Prospect Avenue**. At Lake Street, turn right (east) to Mason Street. Cross the railroad tracks and immediately turn left (north). Just before the parking garage, turn right (east) and take the path that leads to a **tunnel that passes under College Avenue** and comes out at the University Test Gardens. Continue on this path and it will cross Remington Street to the UCA. **Allow 10 minutes to walk**.

C. University Inn Best Western Hotel. Take Elizabeth Street east to Remington Street (one block). Turn right (south) to Pitkin Street. Once you cross Pitkin Street, the University Center for the Arts is to your left. **Allow 5 minutes to walk.**

6. Registration packet. Your registration packet will include the program, name badge, water bottle and a pass for the Fort Collins MAX bus. The pass allows you to ride the bus through Saturday night. Registration also includes lunch for Friday and Saturday. If you are staying in the dorms you will also have breakfast provided at the dorm dining hall, Corbett Hall, which is just east of Alpine Hall where you are staying (please see the attached map).

If you have questions, please contact me and I will address them. Finally, I will be at the American Society for Virology meeting Saturday through Wednesday so my email access may be intermittent.

Thanks and see you next week.

Tony

Subject: Bat Infectious Disease meeting - Fort Collins, CO 29 June - 1 July

Dear Michaeleen,

I wanted to alert you to a conference on bat infectious diseases that's coming up this summer. Not sure if you had heard about it, or if it's something you're interested in attending or covering. I'm cc'ing my colleague Tony Schountz here who is the symposium organizer. I'll be there, along with a bunch of world-renouned bat disease nerds.

CC: Laing, Eric ; Chris Broder ; Luke Hamel ecohealthalliance.org>
Subject: Bat MERS-CoV sera for S protein luminex-based assay R&D

Dear Tony and Vincent,

Hope this finds you both well! I know Vincent is in the Congo, so his responses are delayed.

I'm working on a grant proposal (GHERI) with Chris Border and Eric Laing to do some serological screening and assay development for MERS-CoV and other CoVs using a Luminex-based platform. This builds off the work Broder and crew have already done, but will provide support for additional R&D for the MERS-CoV Spike assay, and for in-country capacity building and testing. The idea is to then use the multiplex CoV assays to screen bat sera that we are currently collecting under a DTRA supported project across Western Asia/Middle East (which I'm PI on, and Vincent is involved with).

In order to validate the MERS-CoV assay during the R&D phase,**it would be super helpful to have some confirmed MERS-CoV positive bat sera to work with**. Given that you guys have run MERS-CoV bat infection trials (and may be doing more?), I'm wondering what the possibility of getting some positive bat sera over to Chris' lab for validation? Also, in reading your paper again I remembered that you observed limited seroconversion in bats at 28 dpi… so maybe this is a moot question? Any additional evidence that supports seroconversion in bats?

The grant is due in a couple of weeks, so at this stage I'm just really looking for a general response if you think this is feasible, so we can throw a line in the proposal. i.e. "In collaboration with Vincent Munster (NIH) and Tony Schountz (CSU) we will validate our MERS S protein assay using positive control bat sera from previous experimental infection studies".

Please let me know your thoughts or any additional ideas.

Cheers,
Kevin

Dear Pat and Eun Chung,
It was wonderful to see you in Ft. Collins. I'm grateful that we had time to talk about this project and for your interest and support. Attached are two briefs which detail the scope of work and scientific rationale for setting up the Pteropus colony. Let's use this as a starting point for further discussion about a potential contract. I'd be happy to provide additional information as per your guidance.

Cheers,
Jon

Draft: Pre-White paper for discussion
Epstein et al. 2016

Establishment of a pteropid bat colony (*Pteropus medius*) in the United States to study host-virus interactions, including the immune response, to Nipah virus and other zoonotic pathogens that threaten human health.

Prepared by
Jonathan Epstein, DVM, MPH, PhD, EcoHealth Alliance
Tony Schountz, PhD, Colorado State University
Dr. Vincent Munster, PhD, NIH NIAID Rocky Mountain Laboratories

Bats have been shown to carry more zoonotic pathogens than any other mammalian taxon (Olival et al, Nature 2017)**.**

Several emerging zoonotic pathogens associated with severe human disease originated, are hosted or suspected to be hosted by bats, including severe acute respiratory syndrome coronavirus (SARS-CoV), Middle East respiratory syndrome coronavirus (MERS CoV), Marburg virus, ebolaviruses, and a wide range of lyssaviruses. We recently found evidence of a SARS-like coronavirus in Chinese horseshoe bats that has the capability to transmit directly to people, which suggests that the original transmission of SARS may have been directly from bats, rather than via civets or other animal intermediate hosts. Recent studies have also found evidence that bats were reservoirs the ancestors of other human pathogens such as hantaviruses, hepatitis C, rubeola, mumps and rubella viruses. Much of this work arose from phylogenetic, epidemiological and virological studies of viruses identified in wild caught bats, including substantial work from our group. These findings have generated larger questions about how bats (the second largest group of mammals with more than 1,200 species) can host these viruses that without substantial pathology, yet they cause substantial disease in other species, including humans.

To determine whether bats have a specialized physiology or immune systems that permit viral infection with minimal disease requires development of bat models that can be used in laboratory experiments.

Bats of the genus *Pteropus* (family Pteropodidae) comprise more than 60 species that range from Madagascar eastward through most of Asia, Australia, and the Pacific islands. Several species of pteropid bats are natural reservoirs of NiV and other henipaviruses, including Hendra virus (HeV) and Cedar virus in Australia. Both Nipah and Hendra viruses are biosafety level 4 pathogens and select agents. Currently, the only captive colony of pteropid bats available for infectious disease research (to our knowledge) exists at the Australian Animal Health Laboratory (AAHL) in Geelong, Australia, which has BSL-4 small and large animal facilities. Although AAHL has developed and will collaboratively share cell lines derived from one species of pteropid bat (*P. alecto*), at present the bats are not available to researchers outside of AAHL. Thus, a significant need remains for a lab animal model that can be used to study NiV and HeV host-virus interactions and generate additional laboratory reagents and resources available to a broader research community.

Pteropus medius, in particular, is of special interest for viral research because it is has been found to carry Nipah virus and other viruses with potential human health impact, including filoviruses and other uncharacterized henipaviruses for which we have serological evidence. This species also carries a recently discovered virus called GBV-D, a flavivirus related to Hepatitis C virus. *The propensity for this particular species to carry a wide spectrum of viruses*

related to known human pathogens (without clinical affect) makes it an ideal candidate as a laboratory model to advance immunological and virological studies in bats.

The establishment of a research colony of Indian flying foxes (*Pteropus medius*) is critical to facilitate research in the United States that will test hypotheses related to the cellular mechanics of Nipah virus (NiV) and the host immune response, *in vivo,* in a wildlife reservoir species for Nipah virus. The Indian flying fox is endemic to the Indian subcontinent, and widely distributed throughout Bangladesh and India, where more than fifteen outbreaks of Nipah virus encephalitis have been reported since 2001. **There are no bats available in the United States for research related to *Pteropus* physiology, immunology, and viral pathophysiology.** NiV is an emerging, high consequence pathogen with 75% - 100% mortality in humans in Bangladesh, where is causes seasonal outbreaks of encephalitis. Currently, there is no effective treatment or vaccine for NiV. It is a highly communicable disease, including person-to-person and nosocomial transmission. Though the majority of outbreaks, to date, have occurred in rural villages, Bangladeshi patients are often transported to Dhaka for care. The introduction of NiV to Dhaka, a city of 12 million people with an international airport linking major cities, including New York, London, and Hong Kong, represents one of the most significant factors contributing to Nipah virus' pandemic potential.

Maintaining bat colonies requires many specialized husbandry facilities and resources. Indeed, insectivorous bats are notoriously difficult to keep, let alone breed in captivity. Frugivorous bats are much easier to maintain in captivity. They are typically robust and will eat a variety of fruits that are readily available in the United States. Their social structure and behavior is well understood, and zoological institutions have successfully kept and bred a variety of fruit bats species, including many different pteropid bat species. [Note: in the context of this proposal, zoological institutions are not a viable source of bats for founding a colony as biomedical research is generally considered "off mission" for zoological gardens focused on species conservation] The Indian flying fox is an attractive bat model because it is a reservoir host of NiV, its large body mass (~700-900g) allows for relatively large volumes of blood and lymphoid cells to be safely sampled to support clinical research, its conservation status is "non-threatened" (thus allowing wild founders to be more readily sourced), and it is easy to maintain and breed in captivity.

2) Who will establish the colony? Where would the bats come from and where would the colony be maintained?

Our group includes experts on the behavior and husbandry of bats, their ecology, the epidemiology of Nipah virus in wild populations, and the design and implementation of experiments involving non-traditional animal models.

Colorado State University is a registered NIAID contractor for establishing lab animal models and will be the location of the proposed bat colony. Tony Schountz, PhD is an Associate Professor in the Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine at CSU. Dr. Schountz previously established a breeding colony of, Jamaican fruit bats *(Artibeus jamicensis)* that has been used for Tacaribe virus and MERS-CoV experimental research. CSU currently has the facilities to establish a colony of *Pteropus medius* and Dr. Schountz and Richard Bowen, DVM, PhD will be responsible for establishing and maintaining the research colony. The Director of Laboratory Animal Services at CSU is Lon Kendall, DVM, PhD, who has overseen the veterinary care of the Jamaican fruit bat colony. Thus, the facilities and staffing expertise are already in place at CSU for working with bat colonies.

Draft: Pre-White paper for discussion
Epstein et al. 2016

Dr. Jonathan Epstein, a veterinary epidemiologist at EcoHealth Alliance, has nearly 20 years of experience working with pteropid fruit bats in the wild. His research has focused on the epidemiology and ecology of Nipah virus and other zoonotic agents in bats. He directed the capture, quarantine and transport of live *Pteropus vampyrus* from Malaysia (another reservoir of Nipah virus) to AAHL as part of an NIH-funded long-term study of henipaviruses in bats in 2005. He has been working in Bangladesh since 2006, and has established strong collaboration with the government of Bangladesh, including the federal wildlife authority. Dr. Epstein, and his team in Bangladesh will be responsible for the capture, quarantine, and transportation of the bats from Bangladesh to CSU (Fort Collins, Colorado). He will also provide guidance for the facility at CSU (e.g., diurnal cycles, feeding, enrichment, etc.). Dr. Epstein is currently collaborating with Drs. Schountz and Munster on bat immunology studies and will continue to provide leadership and scientific engagement in this and future collaborative studies related to bat immunology and virology related to the imported *Pteropus* bats.

Dr. Vincent Munster is a senior scientist in the Laboratory of Virology, Rocky Mountain Laboratories, NIAID, (Hamilton, MT). His work has focused on experimental studies of bat-borne high containment pathogens such as Ebola virus, Nipah virus, SARS-CoV and MERS-CoV. Dr. Munster will facilitate the establishment of the colony, and will be the laboratory lead and co-investigator on all experimental studies utilizing these bats. We will have the support and use of the BSL 4 laboratory and veterinary personnel at RML for experimental work utilizing the bats.

Mr. Brian Pope, the Director of the Lubee Bat Conservancy in Gainesville Florida has more than 12 years of bat husbandry experience at zoological parks, including Disney World's Animal Kingdom, and will provide expert guidance on the regulatory aspects of bat importation and the development of the internal environment for the bat colony. He and his staff will provide training to the veterinary and animal care staff at CSU and RML on the husbandry and care of the bats. Mr. Pope and Dr. Epstein have collaborated for more than five years on bat immunology studies at the Lubee Bat Conservancy, and Dr. Epstein currently serves on Lubee's Scientific Advisory Board.

To found the colony, we propose to import 40 adult *P. medius* from Bangladesh, with the support of the Forestry Department – the federal wildlife agency. We will import 36 pregnant female bats, and 4 males - all seronegative for Nipah virus. A temporary quarantine facility will be constructed by the Forest Department at the Dhaka zoo, where veterinary and animal care staff are available. Bats will be sampled (blood and urine) every three weeks and samples will be sent to RML laboratories and tested for Nipah virus antibodies and RNA using ELISA, SNT, and PCR.. Bats that have three consecutive negative tests will be shipped to CSU. Our group previously transported pteropid bats from Malaysia to Australia for research purposes. *P. medius* is a seasonal breeder, and females within a colony tend to be pregnant all at once, so capturing 35 pregnant females is achievable. The gestation period is six months, and the timing of transport will be such that the bats will be in the fourth month of pregnancy to maximize the safety to the fetus during transport. We expect 80-90% of pregnancies to be maintained during quarantine and shipment, such that the colony will immediately provide about 30 juveniles that could be used for experimental work within 12 months of birth or to continue breeding after 30 months when they reach sexual maturity. The adults will be bred every year (one breeding cycle per year), which will generate a cohort of 20-35 bats each season. Over a period of 3-5 years, we expect to have generated a colony of more than 200 bats that will be available for experimental studies.

3) Long-term sustainability.

Use of the bat colony as well as cell lines derived from bat tissues will be made available to the scientific community. We expect that cell lines will be the most frequently requested products that could be readily shared among the scientific community. Have a supply of primary and immortalized (e.g., large T, hTERT) cell lines in the US will rapidly facilitate research because it will obviate the need for CITES and other import permits when reagents are shipped to other US-based labs. The colony will also benefit conservation efforts by providing genetic material to zoological institutions that have breeding programs for *P. medius* now or in the future.

Support from NIAID will be required to establish and expand the colony over an initial 5-year period. Once the colony is established, we will generate reagents and cell lines that will be made available to other researchers upon request. After the completion of the contract and to support the maintenance of the colony and associated resources, we will establish a modest fee structure for use of the bats and materials derived from the bats, which will be channeled directly back into colony maintenance costs. We will also consider experiments that require the use of bats and will include budget in each proposal that will be used to support maintenance costs. The fee structure could be modeled from the one used by the Lubee Bat Conservancy, or a de novo fee-for-service system will be developed.

Hi Mindy, Billy, Kevin, and Kendra -

I hope your week has gotten off to a good start!

I'm attaching a draft infographic for your review. I've modified the current BSG MAP infographic per your suggestions for a wildlife version. I can also add a logo, QR, and/or website at the bottom if you'd like. Not sure of exactly the best way to portray environmental samples...I was assuming this will comprise activities like passive fecal sample collections...so please let me know if this captures what you had in mind or if there is something else you're envisioning and I can revise accordingly! (BioRender does have an amusing variety of poo icons, but I was trying to keep it classy and professional.)

Take care, and I'll look forward to your feedback.

Best,
Rebekah

Subject: Re: Preventing human-to-bat transmission of SARS-CoV-2 Figure

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Preventing transmission of SARS-CoV-2 from humans to wild mammals

Exposure Risks

Contact exposure
Mammals coming into contact with contaminated hands or equipment

Aerosol exposure
Infectious droplets from handlers holding mammals in close proximity

Environmental exposure
Sharing enclosed, poorly-ventilated spaces with mammals, where virus may persist in the air or on surfaces

MAP your plan to prevent transmission to mammals!

Mitigation Strategies

Minimize

Delay, prioritize, or avoid handling mammals when possible, i.e. collect environmental samples

Assess

Postpone handling mammals if there is a probability that you have been exposed to SARS-CoV-2 or if you have symptoms

Protect

Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures

Hi Kendra -

Thank you! I'm glad you like it! I have a subscription to BioRender for my lab...well worth the investment...so we get unlimited images, don't have the watermark on it, and can export high resolution for use in publications, grants, presentations etc. I started playing around with the free version though just to be sure I liked it, and its been a huge hit with my lab!

Hi Billy,

The pdf version should be editable, so they should be able to work directly on that and then re-save as an image file. As an alternative, if anyone in your working group or OIE has a BioRender license, I can share the infographic file directly with that person through BioRender to edit. Third option - I'm attaching a translation sheet that could be used as a template. It still has the bat infographic language on it, but if this is updated with the French and Spanish translations for the wildlife infographic, feel free to send those translations back to me and I'd be happy to update the infographic.

Hope that helps, and just let me know how you'd like to proceed.

Hi Rebekah and all.

Thanks again for the graphic.

OIE is distributing our joint WHSG/OIE guidelines and also translating it to French and Spanish as they normally do. They would like to change the language in the graphic also but need either the editable file or at least the background images on which they can overlay the French and Spanish. Are either of those something you could provide?

Thanks,

Billy

That's great Rebekah!

Thanks! I'm happy to chat more with you about it, if that's helpful:)

Dear Melinda
That sounds appropriate to me. Our group meets early on Tuesday morning, so I'd like to run this by them then for final agreement, if that's OK, but I don't imagine any objections.

Best
Tigga

Subject: Re: Preventing human-to-bat transmission of SARS-CoV-2 Figure

Dear Rodrigo and Tigga,

I spoke to my colleagues and we would propose to change "bats" to either "mammals" or "wild mammals", change the graphic in the center to include a smaller version of the bat that is there as well as an ape and a mustelid, change the example in the Minimize box from "i.e. implement acoustic surveys" to "i.e. collect environmental samples", and change the figure of the bat calling to a figure of collecting an environmental sample.

The risks and mitigation strategies are really nicely laid out as you originally made it so we wouldn't need to change that or the rest of the text/figures. We support your MAP plan.

Do you think that would be acceptable? We think it remains very consistent with your message.

If yes, what is the best way to proceed with the modification?

Kind regards,

Mindy

Hi everyone

Thank you Tigga for copying me with the good email address. Mindy good talking to you again. I fully concur with Tigga about being mindful of the brains behind the infographic, and of course about any changes. If at all possible Mindy we would rather have it presented with due credits verbatim. Multiple version will be confusing, regardless of whether the different versions clash with each other. Stay safe.

Translation Sheet. Please translate the English to your language as closely as possibly and use the same format for the section. If you can retain the “MAP” – Minimize, Assess, Protect that is ideal, but it of course depends on the translation.
Example

Section	**English**	
Title	**Preventing human-to-bat transmission of SARS-CoV-2**	
Tagline	MAP your plan to prevent transmission to bats	
Heading 1	**Exposure Risk**	
Heading 2	*Contact exposure*	
	Bats coming into contact with contaminated hands or equipments	
Heading 2	*Aerosol exposure*	
	Infectious droplets from handler holding bats in close proximity	
Heading 2	*Environmental exposure*	
	Sharing enclosed, poorly ventilated spaces with bats, where virus may persist in the air or on surface	
Heading 1	**Mitigation strategies**	
Heading 2	*Minimize*	
	Delay, prioritize, or avoid handling bats when possible, i.e. implement acoustic surveys	
Heading 2	*Assess*	
	Postpone handling bats if there is probability that you have been exposed to SARS-CoV-2 or if you have to symptoms	
Heading 2	*Protect*	
	Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures	

EXAMPLE

Section	English	LANGUAGE
Title	**Preventing human-to-bat transmission of SARS-CoV-2**	**Cegah Penularan SARS-CoV-2 dari manusia-ke-kelelawar**
Tagline	MAP your plan to prevent transmission to bats	**KENAL**[1] dan rencanakan pencegahan penularan ke kelelawar [1]KENAL: Kurangi, Nilai dan Lindungi Note: Kenal in Indonesia means know, be familiar
Heading 1	**Exposure Risk**	**Risiko Paparan**
Heading 2	*Contact exposure*	*Paparan kontak*
	Bats coming into contact with contaminated hands or equipments	Kelelawar kontak langsung dengan tangan atau peralatan yang terkontaminasi
Heading 2	*Aerosol exposure*	*Paparan aerosol*
	Infectious droplets from handler holding bats in close proximity	Droplet infeksius dari pemegang kelelawar dalam jarak dekat
Heading 2	*Environmental exposure*	*Paparan lingkungan*
	Sharing enclosed, poorly ventilated spaces with bats, where virus may persist in the air or on surface	Berada satu tempat dengan kelelawar di ruang tertutup, dan minim ventilasi dimana virus dapat bertahan di udara atau di permukaan benda
Heading 1	**Mitigation strategies**	**Strategi mitigasi**
Heading 2	*Minimize*	*Kurangi*
	Delay, prioritize, or avoid handling bats when possible, i.e. implement acoustic surveys	Menunda, memprioritaskan, atau sebisa mungkin hindari memegang kelelawar, misalnya menerapkan survei akustik

Heading 2	*Assess*	*Nilai*
	Postpone handling bats if there is probability that you have been exposed to SARS-CoV-2 or if you have to symptoms	Tidak memegang kelelawar jika anda merasa ada kemungkinan terinfeksi SARS-CoV-2 atau memiliki gejala
Heading 2	*Protect*	*Lindungi*
	Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures	Lakukan tindakan yang dapat mengurangi paparan, seperti menggunakan pelindung wajah, masker, sarung tangan, dan langkah desinfeksi

Preventing transmission of SARS-CoV-2 from humans to wild mammals

Exposure Risks

Contact exposure
Mammals coming into contact with contaminated hands or equipment

Aerosol exposure
Infectious droplets from handlers holding mammals in close proximity

Environmental exposure
Sharing enclosed, poorly-ventilated spaces with mammals, where virus may persist in the air or on surfaces

MAP your plan to prevent transmission to mammals!

Mitigation Strategies

Minimize

Delay, prioritize, or avoid handling mammals when possible, i.e. collect environmental samples

Assess

Postpone handling mammals if there is a probability that you have been exposed to SARS-CoV-2 or if you have symptoms

Protect

Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures

This figure was adapted in collaboration with the IUCN Bat Specialist group.

Subject: Reference for Anna Fagre for EID-Search Research Scientist & Project Manager at EcoHealth Alliance

Dear Dr. Kading,

We just interviewed Anna Fagre for a position here at EcoHealth Alliance as a Research Scientist and Project Manager. Our hiring committee thought she was terrific with the right background and attitude for our team. Anna listed you as a reference. If you would be willing to send some comments about Anna, that would be terrific!

I have attached our position advertisement, so you may know more about the position - though based on her skillset, the specifics would evolve a bit. This position would focus primarily on our emerging infectious disease projects based in Southeast Asia including our recently awarded, NIAID funded EID-SEARCH program:

- https://www.ecohealthalliance.org/program/south-east-asia-research-collaboration-hub

I look forward to your reply and should a phone call be more convenient, we could do that as well.

On behalf of our whole committee, I sincerely appreciate your time.

Subject: Re: Reference for Anna Fagre for EID-Search Research Scientist & Project Manager at EcoHealth Alliance

Dear Aleksei, Peter, and Hongying,

I enthusiastically recommend Dr. Anna Fagre for the Research Scientist and Project Manager position at EcoHealth Alliance.

To speak to Anna's **research experience and capability**: I've known Anna since I joined the CSU faculty in 2016, when she arranged to a rotation as part of her microbiology residency. Anna formally joined my laboratory as a PhD student in July 2017. Her dissertation is focused on the role of bats as reservoirs of emerging arboviruses, and she has made significant progress on both *in vitro* and *in vivo* studies involving bat-associated orbiviruses. The primary emphasis of these studies is on characterization of Bukakata orbivirus, a novel virus that I isolated from a fruit bat in Uganda in 2013. Bukakata orbivirus is putatively tick-borne, based on the phylogenetic analyses we have conducted. To study this virus in the broader context of other orbiviruses that have been isolated from naturally-infected bats, we acquired all three of the remaining bat-associated orbiviruses from the CDC reference collection as well as Chobar Gorge virus, a tick-borne orbivirus to which Bukakata appears to be closely related. Anna's molecular and phylogenetic characterization of Bukakata and other bat-associated orbiviruses was published in a special collection on bat viruses, in the journal Viruses (PMID: 30832334) along with a comprehensive review of the potential for bats to serve as reservoirs for arboviruses (PMID: 30832426). Since the time these papers were completed, Anna has also put significant effort into investigating the use of subgenomic RNA derived from the 3'UTR of flaviviruses to look for evidence of past infection in archived tissue samples. Because of the complex hairpin structure of the viral RNA in the 3'UTR, it is protected from RNA degradation by the exonuclease XRN1, so we hypothesized that we would find residual viral RNA that could be amplified and sequenced. After optimizing this methodology, Anna screened all of our remaining bat tissue samples from Uganda, going back 10 years, and discovered that 4 bats between 2009 – 2013 had been infected with Zika virus. Moreover, this Zika virus sequence was most similar to the Asian lineage, suggesting either diversification of Zika virus strains prior to the virus expanding into Asian in the ~1960s or spillback into Africa of the epidemic strain much earlier than we have appreciated. This manuscript is currently in review. All in all, Anna's work in my lab has been top-notch. She is meticulous and hard-working and has an excellent grasp of the molecular methodologies and big picture of how they can be applied innovatively in an ecological context. In each of these projects, she has done an excellent job leading, and taken initiatives beyond the original study scope that have made the work much stronger in the end. Her **background in veterinary medicine** has also added valuable perspective, and been very much in-demand as she has helped other laboratories on campus during this pandemic with *in vivo* studies involving SARS-CoV-2.

Other key attributes relevant to the current opportunity:

Anna is highly **collaborative,** personable, and very proactive in seeking these collaborations. This year she has re-connected with a former CSU graduate school colleague who is now in Bangladesh, and has been actively developing some research ideas and using her own funding to generate preliminary data. She also joined the VERENA consortium and has been working on a review paper with collaborators in that group. She works very well with others, as a leader of diverse teams as well as a contributing member. She has had the opportunity to contribute to a number of **international projects** both as part of my lab and during her previous experience, and is very adaptable, capable, and enthusiastic about working internationally. Over the past year she has been an invaluable member of an global initiative led by the CSU Office of the Vice President for Research, and has earned the respect of the highest CSU leadership for her contributions to this team.

Anna has been successful at **securing extramural funding**, of her own initiative. Since joining my lab, she has been awarded three highly-competitive fellowships and grants: An NIH TL1 fellowship through the Colorado Clinical and Translational Science Institute, a spot on the NIH T32 award to CSU, and the 2019 Robert E. Shope International Fellowship in Infectious Diseases through ASTMH/ACAV.

Anna is an excellent writer and **science communicator**, and also publishes frequently on blogs and other social media platforms in addition to her prolific peer-reviewed publications. She is the literature watchdog of the lab, and somehow seems to know about every relevant paper or report that is published within a half hour of it hitting the press. Anna has excellent soft skills when interacting with other professionals. She was featured in a documentary video made by CSU, and had a very natural presence and ability to clearly explain her research and general principles of disease ecology in lay terms.

In conclusion, I give Anna my highest recommendation and think she would be a fantastic addition to your team. Anna is extremely proactive, self-motivated, skilled, and has brought a wonderful energy and work ethic to my laboratory. She is an up-and-coming leader in the field, and I am thrilled to have her as part of my team. This turned out to be not-so-brief a recommendation, but I hope was a useful assessment! If you have any questions or if I can be of any additional assistance, please do not hesitate to contact me.

Subject: RE: SARS-CoV-2 spillback risk to North American bats

Hi Paul
Very interested to see the MS. Rebekah and I have been working on something that arose out of BOHRN that would be very complementary and might be worth trying to coordinate dissemination in some way. We are meeting today and will take stock of where we are at.

I just started an email to you and Kevin about the state of affairs as we Rodrigo and I are getting quite a bit of push-back on the IUCN BSG recommendation to suspend field studies while further data are gathered (primarily from western scientists with access to PPE). It would be good to hear what those committees are finding sooner rather than later.

Best wishes

Subject: SARS-CoV-2 spillback risk to North American bats

Hi Tigga,

Sorry for the silence since my call for help about the risks of humans potentially infecting bats in North America with the SARS-CoV-2 virus. Thanks for your patience and willingness to get involved in what we're hoping can be another disease response where scientists coming at disparate aspects of bats and pathogens can help each other. Those of us in the bat research world that focused most of our past efforts in the U.S. on conservation and management of bat populations can certainly use your expertise and help adjusting to the new situation.

A lot happened during my silence. Another group in USGS has been working at the behest of decision makers across federal and state natural resource management agencies to pull off a formal risk assessment by querying a subset of the experts we've reached out to. You lucked out and were not chosen for that exercise (yet), but we will keep you posted on the outcomes of that rapid assessment.

The other thing keeping me silent over the past couple of weeks is a short manuscript (currently 5 pages single spaced) that Kevin Olival and I drafted to articulate the potential risks of humans infecting North American temperate-zone bats with SARS-CoV-2, potentially relevant patterns we observed in bat-CoV distributions at a global scale, and the likely benefits of

disease and bat researchers working together to draw on the strengths of our various disciplines. We hope to have a draft to circulate by tomorrow and would appreciate input and feedback from any of you willing to read it and help us stress test the concepts and assertions therein. Please let me know if you are interested.

Thanks again for your help and patience.

All the best,
Paul

Greetings everyone! Thank you for the update - I will stay tuned to see how the situation unfolds. I am available on those dates should that work out. We could try a Zoom meeting sometime in the interim, if that would be helpful to get everyone "together"? I know many BOHRN members have been collaborating and contributing to the pandemic response in a variety of ways, which I think represents some successful grassroots mobilization of the network. Might be encouraging to have something of a group call to hear about what folks have been up to and if there's anything we can band together more formally to accomplish despite being scattered. Just an idea to throw out there!
Kind regards,
Rebekah

Dear BOHRN TRN Steering Committee Members,

We hope you have been able to remain safe during these times and that this email finds you well. As you may already know, the World One Health Congress has been rescheduled to take place on October 30 - November 3 in response to worldwide travel restrictions and to coincide with International One Health Day on November 3rd. We wanted to inform you that the BTRP TRN side meetings have been rescheduled in tandem with the Congress, now aiming to take place on November 3 - 4. This is a change we are trying to implement, however, we understand the current scope of world events and anticipate further changes as we go forward. Our utmost priority is everyone's safety and we will continue to monitor the situation to act accordingly. We will be sure to keep you informed of all updates.

Please let us know if you have any questions and stay safe.

Kind Regards,

GSE Logistics Team

Subject: World One Health Congress and BTRP TRN Side Meeting - BOHRN

Dear BOHRN TRN Steering Committee Members,

On behalf of Dr. Martha Stokes, please accept this Save the Date to attend the World One Health Congress in Edinburgh, Scotland 15-17 June 2020 and participate in side meetings on BTRP's Threat Reduction Networks and planning for BOHRN.

Tentatively, we plan to hold two sessions at the end of the week: Thursday, 18 June - an afternoon TRN session that will include a wide group of BTRP-funded participants from its other research networks to discuss network metrics for sustainability; Friday, 19 June - a side meeting for BOHRN to map out its schedule and strategy, aligning with funding opportunities from BTRP and other entities. Attached is a tentative schedule for the week, for your reference. Due to travel and budgetary constraints we are unable to invite the entire steering committee, but intend to have productive discussions and meet objectives with the smaller group on this Save the Date email.

Please let us know if you will be able to attend the WOHC and side meetings on 18-19 June. Official invitation with travel instructions, details on arrangements, and more formal agenda will be forthcoming. Please note that there is a potential for the WOHC and BTRP side meetings to be postponed, given the current travel uncertainties related to COVID-19. We will be monitoring the status of the conference, and will keep you apprised of any cancellations should they occur. As always, let us know if you have any questions!

We hope to see you in Edinburgh!!

V/r,
Caitlin Devaney

Dear Caitlin, and hello everyone,

Thank you very much for the invitation! I would very much like to attend and participate in these discussions regarding BOHRN, but I have a couple of complications. Colorado State University currently has a restriction on international travel until further notice, but it's hard to know what things will be like in June. Hopefully that would be lifted by then. These dates also overlap with the Infectious Diseases of Bats Symposium being held at CSU June 17-19 after the American Society for Virology meeting, and I confirmed awhile ago I would participate in the bat meeting here. I think I should honor that existing commitment, which means I will not be able to attend the BOHRN steering committee meeting in Edinburgh. If this affects more steering committee members than just me, would having the BOHRN meeting in conjuction with the bat ID be a possibility? I understand if not, and I will look forward to catching up with everyone at the next opportunity!

Best regards,
Rebekah

Dear Marty, Katie, Megan, Jon, and Tigga -

I just wanted to send a quick message to thank you for all your hard work on our BOHRN meeting last week! I know that took an amazing amount of coordination to get so many more people there, and I thought it was a very productive time! It was nice to have formal talks from some folks, and the white paper exercise was a great way to get people working together. I appreciate all the time and energy you each put into BOHRN -- it is a unique group with an important purpose and I am excited about the trajectory we are on so far! I'll look forward to touching base again soon about planning the Uganda meeting in the spring.

Take care and have a great week -

Best regards,
Rebekah

Subject: BPERNet Side Meeting / PMAC

All,

By now you should have received a letter of invitation from the PMAC Organizing Committee. Please log-on and sign up to the sessions that you can attend. Our side meeting will be on the 30th at Chula Hospital. If you have confirmed attendance with us, then you should have already contacted Nicki Aleman (copied). If not, and you require travel assistance, please email me and her.

CBEP is still covering your air travel, transport to and from the airport, and hotel arrangements, so please ignore those instructions in your PMAC invitation.

Please let me know if you have any questions.

Subject: Reception at U.S. Embassy (Context)

All,

You likely received an invitation from “Protocol Bangkok” inviting you to a Prince Mahidol Award Reception at the U.S. Ambassador’s residence on Thursday, February 1 from 1800 – 2000.

Here is a bit of context about the event: this year, the United States became the first country to receive awards in all categories of the Prince Mahidol Awards, which are awarded annually under patronage of the Thai Royal Family to individuals and organizations that have made outstanding contributions to medicine and public health. Historically, winners have been forerunners to Nobel prizes. This year’s American awardees include the Human Genome Project and a team of researchers who developed a vaccine against Haemophilus influenza.

The U.S. Ambassador is not only proud of this historic American accomplishment, but would also like to use the opportunity to highlight the U.S. Government’s long history of military and civilian cooperation on health issues in Thailand and the greater region. The 60-year history of U.S. – Thai health cooperation is one of the lesser told success stories of the long-standing relationship with a close regional ally; and further, an alignment with the 200-year anniversary of U.S. – Thai friendship, which also occurs in 2018.

CBEP is very much a contributor to U.S.-Thai military and civilian cooperation and accomplishment on health issues; therefore, Dr. Stokes and her colleagues are co-sponsoring the celebration at the Ambassador’s residence and provided your names as their guests to the event. On behalf of her and the CBEP delegation, we very much hope you will attend.

Please let me know **if you did not receive an invitation**. Please also let me know if you have any questions. Otherwise, please follow the instructions in your invitation for favorable response.

Thank you!

V/r,

Katie Leahy

Subject: Bat Facility meeting
Location: Microsoft Teams Meeting

Start: Tuesday, March 31, 2020 12:00 PM EDT
End: Tuesday, March 31, 2020 1:00 PM EDT
Show Time As: Tentative

Recurrence: None

Meeting Status: Not yet responded

Organizer: Kendall,Lon
Required Attendees: Kendall,Lon ; Angela Bosco-Lauth >; Bowen,Richard ; Dean,Gregg ; epstein ecohealthalliance.org>; Schountz,Tony >; Szalai,Edit >; bpope jean.patterson >; mchallberg < ; Ebel,Greg >; Cassetti, Cristina (NIH/NIAID) [E]

Here is tomorrow's agenda. Talk to you all tomorrow. You should be able to join by clicking the link below.
Introduction
Lon- why meeting was initially organized, then turf to Jon (I won't be long)
Jon- provide background about program discussions with CSU and NIAID and why we are here (Jon really sparked this discussion, and is probably best to lead)
Jean- Discuss NIAID possibilities and expectations and what's needed from CSU (Thought Jean should go sooner to help frame discussion below. I will send her agenda once we get it finalized)
Ebel- Discuss CVID abilities, and possibilities related to emerging disease, prior C06
Tony- Discuss current research and potential needs
Bowen/Angela- Discuss current research and potential needs
Determine next steps

Subject: Monoclonal antibodies

Jon, I think a really important part of the grant will be to make monoclonal antibodies to various proteins (e.g., CD antigens, cytokines) and cytokines as reagents. If you agree, I'd like to approach a colleague of my, Brian Geiss, to see if he is willing to be on the grant. Recombinant protein expression is his "thing" and he would be a great asset for the grant.

I also think we should get as many letters of support that we can get. I can probably get at least 10 from people we've helped over the years (provided tissues and cells, conducted experimental infections, etc.).

Let me know what you think.

Just moved into our new building. It is really sweet. :)

Thanks,

T.

It would be a great idea to have another building in-country for housing and staging bats for quarantine before shipping to USA.

Getting on a call with DARPA in a few minutes, so won't be responsive for an hour or so.

Awesome - and agree.
I would like to brainstorm together for the letters before we approach anyone. I'll start a google doc and we can live edit it.
Let's think about who the 'dream team' will be for this.
It also occurred to me - what do you think about building in a facility in Bangladesh where we keep a captive breeding colony, that would serve as a feeder if we need more bats along the way? We could develop and fund a closed colony there, like what Cambridge did in Ghana, and we'd know the status of each bat. Brian Pope would be great at helping set this up. And it would allow the colony at CSU to fluctuate a bit in size, and we could pull in new bats as needed. I think it's a nice insurance policy to support the colony in CO as we develop it. This could be something I would manage - but I think we could convince the govt and if we provide all the funding for construction and upkeep, it could really happen.

Thoughts?

Hi Tony, Jon, and Greg;
Here are the example R24's you may want to look up in NIH Reporter:

R24AI059830 PI: Jacques Robert (University of Rochester, animal model containing)
R24AI120942 PI: Scott Weaver (University of Texas Medical Branch, WRCEVA—no model development but may be relevant if thinking about including training; may also be good to link in with them for potential distribution of critical reagents along with BEI Resources)

As Mark mentioned on the phone, NIAID doesn't allow a lot of R24 grants and thus not many are funded, so there aren't many relevant examples to what you would be putting forth in your R24. Please let me know if you have other questions or concerns!
Happy writing 😊
Sincerely, Sara

Dear Ben,

Your abstract submission has been accepted for a **POSTER** presentation. The session is **Friday, April 30 from 12:00 to 2:00 PM** in the University Center for the Arts. The maximum size of your poster **should not exceed 122 cm/48 inches height and width**. We will provide push pins for mounting your poster on the easel. If you have questions, please feel free to contact me.

Thank you and we look forward to your presentation.

Dear Dr. Shi,

We have you scheduled to give a 15 min talk (12 minutes plus 3 minutes for questions) at the bat infectious diseases symposium, probably Friday morning, June 30. I should have the program draft up next week.

Thanks,

Tony

Dear Tony,

Thank you for your organizing the nice bat ID symposium. We enjoy very much th discussion with the scientists of different speciality.

Thank you for your considering to participate in the meeting "8th International symposium on emerging viral dieases" to be held in Wuhan in Ocotber, 2018. We will add you at the email distribution list and let you know as soon as we have a fixed date. Usually, the meeting will be held at the 4th week with the duration of 3 days (with 2 days of scientifc activity).

Looking forward to meeting you again,

Best regards,
Zhengli,

Hi Zhengli,

I hope your travel home was peaceful. I wanted to thank you for your attendance and presentation at the bat ID symposium. I think it was a very good meeting and I hope others benefited from it. We are already planning to host it again in 2020.

If you have an email distribution list for the conference you're hosting next year, could you please add me to it? It looks like a great meeting and if I can get travel arranged I would like to come.

Thank you,

Tony

Subject: Bat Facility meeting
Location: Microsoft Teams Meeting

Start: Tuesday, March 31, 2020 12:00 PM EDT
End: Tuesday, March 31, 2020 1:00 PM EDT
Show Time As: Busy

Recurrence: None

Meeting Status: Not yet responded

Organizer: Kendall,Lon
Required Attendees: Kendall,Lon >; Angela Bosco-Lauth < >; Bowen,Richard < ; Dean,Gregg ; epstein ecohealthalliance.org>; Schountz,Tony >; Szalai,Edit bpope < >; jean.patterson ; mchallberg >; Ebel,Greg >; Cassetti, Cristina (NIH/NIAID) [E]

Here is tomorrow's agenda. Talk to you all tomorrow. You should be able to join by clicking the link below.
Introduction
Lon- why meeting was initially organized, then turf to Jon (I won't be long)
Jon- provide background about program discussions with CSU and NIAID and why we are here (Jon really sparked this discussion, and is probably best to lead)
Jean- Discuss NIAID possibilities and expectations and what's needed from CSU (Thought Jean should go sooner to help frame discussion below. I will send her agenda once we get it finalized)
Ebel- Discuss CVID abilities, and possibilities related to emerging disease, prior C06
Tony- Discuss current research and potential needs
Bowen/Angela- Discuss current research and potential needs
Determine next steps

Subject: Action needed: check your proof 10.1093/infdis/jiz648

Dear Dr. Vincent Munster,

You must check your proof now to avoid delaying publication.

What you need to do now:

1. Access your proof https://pubkit.newgen.co/auth_token_login/af89fcf9-b35f-40b5-a782-420952f1a4a4

2. Respond on the proof to any copyeditor queries.

3. Approve your proof for publication or submit minor formatting corrections within one working day.

Please note that this is causing a delay to the publication of your manuscript. Please contact us if you need any help.

Best wishes,

The Journal of Infectious Diseases production team

Subject: Agenda of the 8th International Symposium of Emerging Viral Diseases
Attachment(s): "Program of the 8th ISEVD.pdf"

Dear speaker:

We have made the program for our emerging virus symposium. Your presentation is scheduled in the afternoon of 21st October, in the session "emerging viral pathogens".

I have attached the program for your information.

We have reserved accommodation for you at the conference venue, Optic Valley Plaza hotel. Please provide me your flight information once it is available, and we will arrange pick-up service at the airport.

Also, please send me your update CV by 7th October, as we would like to include the CV of our speakers together with the abstracts in the conference proceedings.

Thank you!

Best wishes

Ben Hu Ph.D

Wuhan Institute of Virology, CAS
Secretary of the 8th ISEVD

Subject: ASCB/EMBO Online Meeting

Dear All,

I would like you to consider submitting abstracts to the 2020 ASCB/EMBO Meeting, which will go virtual.
https://www.ascb.org/cellbiovirtual2020/program/

I will be co-chairing a mini-symposium in the scientific track, Cells in Distress and Disease

My initial proposal focused on host-pathogen interactions at a molecular level.

We are currently accepting abstracts for consideration to give a talk in the 2020 Minisymposia.

The deadline for submission is July 30.
https://www.ascb.org/cellbiovirtual2020/abstracts

PLEASE SHARE THIS INFORMATION WITH OTHER COLLEAGUES WHO MAY BE INTERESTED. THANKS

All the best, Roberto

Professor Roberto Bruzzone
Co-Director
HKU-Pasteur Research Pole
School of Public Health
LKS Faculty of Medicine
The University of Hong Kong

Subject: Bat Challenge

Hi Tony,

Sorry for late notice, but I didn't want to promise something this time without following through, so Simon (Anthony) can actually vouch for me.

STRICTLY CONFIDENTIAL-For your eyes (and ears) ONLY.
If you are free tomorrow at about 4 pm EST, can you Skype or Zoom in (I'm sure Jon Epstein can figure something out). I'm presenting data to relevant company at EcoHealth Alliance.

Anything bat-related is, of course, hot right now. So, this time, if you agree to help, yours will be the last experiment, not the first.

Meanwhile, if you get this message in time, can you let us know (Simon and Jon is CC-ed on this email) what species of bat you have in your colony? It's important for us to check something before hand.

Thanks! (Again, I apologize for the short notice, what's left of my life has been consumed by my second full-time job on Twitter)

Best regards,

Benhur

Subject: Bat housing

All,

Alan asked me to follow up on the renovations of the bull barn for bat holding. I did a quick space assessment of the building. It is approximately 2500 sf, including a 100 sf storage area. I am assuming of the 2500 sf we'll need about 500 sf for storage, feed prep and procedure space. The AZA recommendations for Pteropus giganteus is 15'x30' per 6 bats. With 2000 sf, that leave us holding for 24-29 bats. If there are some other housing guidelines someone has, please let me know.

On the call we discussed 40-60 bats. I'm looking for advice on how to proceed. We can look at extending the footprint to accommodate 40-60, but I'm not sure what the program needs will be.

Thanks,

Lon

Subject: Bat ID Symposium logistics
Attachment(s): "Campus map.pdf"

Dear Colleagues,

The symposium is one week away and I want to provide you with some logistical information for your arrival to Fort Collins.

1. Speakers. If you can email your presentation directly to me I will get it on the computer for the presentation**However, the file size must be less than 15 MB to accommodate our email server limit**. Otherwise, please bring your presentation on a USB drive if it is larger than 15 mb. We will have both Microsoft Power Point and Apple Keynote software for your presentations. **Bring your USB drive to the Thursday evening reception if you want to transfer it then.**

2. Poster presenters. The maximum size of the posters is 48” x 48” (120 cm x 120 cm). We will provide push pins to mount your poster on the easels. When you register, your poster will have a number assigned to it that corresponds to the easel number. Please mount your poster on that easel. **Bring your poster to the Thursday evening reception.**

3. Getting to Fort Collins. Those of you who are flying to Denver International Airport can schedule a ride with the **Green Ride Airport Shuttle** service. Please visit its web site (https://greenrideco.hudsonltd.net/) to make arrangements convenient for your flight schedules. There is a Green Ride desk in the main terminal at the airport with employees that can help you find the bus pickup. The bus ride is about 1 hour and 15 minutes. On the web site, in the box “Dropoff location” choose the appropriate destination from the pull-down menu. For those of you staying in the university dormitories it is “FC - Laurel Village”, the Hilton Hotel near campus is “FC - Hilton Ft Collins”, and the University Inn is “FC - Best Western University Inn”. And just to make you aware, afternoon and evening flights into Denver can be rather bumpy!

4. Weather and Climate. Fort Collins has lots of sunshine and is at 5000 ft/1500 meters. If you intend to be outdoors much you should bring sunscreen. We often get afternoon thunder showers in our otherwise dry climate but they are typically not more than an hour or two and it usually clears up afterwards. You may want to bring rain gear or a small umbrella. The current forecast is for the mid to high 80sF/low 30sC.

5. Getting to the UCA. The conference venue is the **University Center for the Arts (UCA)** (attached map, blue box, lower right). Oral and poster presentations will be in this building and directions will be posted inside. After you get settled in Thursday, please come to the UCA for the opening registration and social mixer by 5:30 PM. Walking paths (routes) are noted in blue hatched lines.

A. Laurel Village Alpine Dormitory. Those who are staying in campus housing, walk south to Plum Street and turn east to Meridian Avenue. Take Meridian Avenue south to Pitkin Street and take it east to Mason Street. Cross the railroad tracks and immediately turn right (south) just before the parking garage. Follow the path to just past the parking garage and turn left (east). This path leads to a **tunnel that passes under College Avenue** and comes out at the University Test Gardens (lots of flowers). Continue on this path and it will cross Remington Street to the UCA. **Allow 15-20 minutes to walk**.

B. Hilton Hotel. Proceed from the hotel to Prospect and Centre Avenue at the northwest corner of the Hilton Hotel parking lot. Cross Centre to the west and **take the tunnel under Prospect Avenue**. At Lake Street, turn right (east) to Mason Street. Cross the railroad tracks and immediately turn left (north). Just before the parking garage, turn right (east) and take the path that leads to a **tunnel that passes under College Avenue** and comes out at the University Test Gardens. Continue on this path and it will cross Remington Street to the UCA. **Allow 10 minutes to walk**.

C. University Inn Best Western Hotel. Take Elizabeth Street east to Remington Street (one block). Turn right (south) to Pitkin Street. Once you cross Pitkin Street, the University Center for the Arts is to your left. **Allow 5 minutes to walk.**

6. Registration packet. Your registration packet will include the program, name badge, water bottle and a pass for the Fort Collins MAX bus. The pass allows you to ride the bus through Saturday night. Registration also includes lunch for Friday and Saturday. If you are staying in the dorms you will also have breakfast provided at the dorm dining hall, Corbett Hall, which is just east of Alpine Hall where you are staying (please see the attached map).

If you have questions, please contact me and I will address them. Finally, I will be at the American Society for Virology meeting Saturday through Wednesday so my email access may be intermittent.

Thanks and see you next week.

Tony

Subject: Bat Infectious Disease meeting - Fort Collins, CO 29 June - 1 July

Dear Michaeleen,

I wanted to alert you to a conference on bat infectious diseases that's coming up this summer. Not sure if you had heard about it, or if it's something you're interested in attending or covering. I'm cc'ing my colleague Tony Schountz here who is the symposium organizer. I'll be there, along with a bunch of world-renouned bat disease nerds.

Subject: Bat MERS-CoV sera for S protein luminex-based assay R&D

Dear Tony and Vincent,

Hope this finds you both well! I know Vincent is in the Congo, so his responses are delayed.

I'm working on a grant proposal (GHERI) with Chris Border and Eric Laing to do some serological screening and assay development for MERS-CoV and other CoVs using a Luminex-based platform. This builds off the work Broder and crew have already done, but will provide support for additional R&D for the MERS-CoV Spike assay, and for in-country capacity building and testing. The idea is to then use the multiplex CoV assays to screen bat sera that we are currently collecting under a DTRA supported project across Western Asia/Middle East (which I'm PI on, and Vincent is involved with).

In order to validate the MERS-CoV assay during the R&D phase,**it would be super helpful to have some confirmed MERS-CoV positive bat sera to work with**. Given that you guys have run MERS-CoV bat infection trials (and may be doing more?), I'm wondering what the possibility of getting some positive bat sera over to Chris' lab for validation? Also, in reading your paper again I remembered that you observed limited seroconversion in bats at 28 dpi… so maybe this is a moot question? Any additional evidence that supports seroconversion in bats?

The grant is due in a couple of weeks, so at this stage I'm just really looking for a general response if you think this is feasible, so we can throw a line in the proposal. i.e. "In collaboration with Vincent Munster (NIH) and Tony Schountz (CSU) we will validate our MERS S protein assay using positive control bat sera from previous experimental infection studies".

Please let me know your thoughts or any additional ideas.

Cheers,
Kevin

Attachment(s): "Establishing a bat colony in the US_Epstein_v3.docx","Pteropus bat model_research justification_2017.docx"

Dear Pat and Eun Chung,
It was wonderful to see you in Ft. Collins. I'm grateful that we had time to talk about this project and for your interest and support. Attached are two briefs which detail the scope of work and scientific rationale for setting up the Pteropus colony. Let's use this as a starting point for further discussion about a potential contract. I'd be happy to provide additional information as per your guidance.

Cheers,
Jon

Draft: Pre-White paper for discussion
Epstein et al. 2016

Establishment of a pteropid bat colony (*Pteropus medius*) in the United States to study host-virus interactions, including the immune response, to Nipah virus and other zoonotic pathogens that threaten human health.

Prepared by
Jonathan Epstein, DVM, MPH, PhD, EcoHealth Alliance
Tony Schountz, PhD, Colorado State University
Dr. Vincent Munster, PhD, NIH NIAID Rocky Mountain Laboratories

Bats have been shown to carry more zoonotic pathogens than any other mammalian taxon (Olival et al, Nature 2017)**.**

Several emerging zoonotic pathogens associated with severe human disease originated, are hosted or suspected to be hosted by bats, including severe acute respiratory syndrome coronavirus (SARS-CoV), Middle East respiratory syndrome coronavirus (MERS CoV), Marburg virus, ebolaviruses, and a wide range of lyssaviruses. We recently found evidence of a SARS-like coronavirus in Chinese horseshoe bats that has the capability to transmit directly to people, which suggests that the original transmission of SARS may have been directly from bats, rather than via civets or other animal intermediate hosts. Recent studies have also found evidence that bats were reservoirs the ancestors of other human pathogens such as hantaviruses, hepatitis C, rubeola, mumps and rubella viruses. Much of this work arose from phylogenetic, epidemiological and virological studies of viruses identified in wild caught bats, including substantial work from our group. These findings have generated larger questions about how bats (the second largest group of mammals with more than 1,200 species) can host these viruses that without substantial pathology, yet they cause substantial disease in other species, including humans.

To determine whether bats have a specialized physiology or immune systems that permit viral infection with minimal disease requires development of bat models that can be used in laboratory experiments.

Bats of the genus *Pteropus* (family Pteropodidae) comprise more than 60 species that range from Madagascar eastward through most of Asia, Australia, and the Pacific islands. Several species of pteropid bats are natural reservoirs of NiV and other henipaviruses, including Hendra virus (HeV) and Cedar virus in Australia. Both Nipah and Hendra viruses are biosafety level 4 pathogens and select agents. Currently, the only captive colony of pteropid bats available for infectious disease research (to our knowledge) exists at the Australian Animal Health Laboratory (AAHL) in Geelong, Australia, which has BSL-4 small and large animal facilities. Although AAHL has developed and will collaboratively share cell lines derived from one species of pteropid bat (*P. alecto*), at present the bats are not available to researchers outside of AAHL. Thus, a significant need remains for a lab animal model that can be used to study NiV and HeV host-virus interactions and generate additional laboratory reagents and resources available to a broader research community.

Pteropus medius, in particular, is of special interest for viral research because it is has been found to carry Nipah virus and other viruses with potential human health impact, including filoviruses and other uncharacterized henipaviruses for which we have serological evidence. This species also carries a recently discovered virus called GBV-D, a flavivirus related to Hepatitis C virus. *The propensity for this particular species to carry a wide spectrum of viruses*

related to known human pathogens (without clinical affect) makes it an ideal candidate as a laboratory model to advance immunological and virological studies in bats.

The establishment of a research colony of Indian flying foxes (*Pteropus medius*) is critical to facilitate research in the United States that will test hypotheses related to the cellular mechanics of Nipah virus (NiV) and the host immune response, *in vivo,* in a wildlife reservoir species for Nipah virus. The Indian flying fox is endemic to the Indian subcontinent, and widely distributed throughout Bangladesh and India, where more than fifteen outbreaks of Nipah virus encephalitis have been reported since 2001. **There are no bats available in the United States for research related to *Pteropus* physiology, immunology, and viral pathophysiology.** NiV is an emerging, high consequence pathogen with 75% - 100% mortality in humans in Bangladesh, where is causes seasonal outbreaks of encephalitis. Currently, there is no effective treatment or vaccine for NiV. It is a highly communicable disease, including person-to-person and nosocomial transmission. Though the majority of outbreaks, to date, have occurred in rural villages, Bangladeshi patients are often transported to Dhaka for care. The introduction of NiV to Dhaka, a city of 12 million people with an international airport linking major cities, including New York, London, and Hong Kong, represents one of the most significant factors contributing to Nipah virus' pandemic potential.

Maintaining bat colonies requires many specialized husbandry facilities and resources. Indeed, insectivorous bats are notoriously difficult to keep, let alone breed in captivity. Frugivorous bats are much easier to maintain in captivity. They are typically robust and will eat a variety of fruits that are readily available in the United States. Their social structure and behavior is well understood, and zoological institutions have successfully kept and bred a variety of fruit bats species, including many different pteropid bat species. [Note: in the context of this proposal, zoological institutions are not a viable source of bats for founding a colony as biomedical research is generally considered "off mission" for zoological gardens focused on species conservation] The Indian flying fox is an attractive bat model because it is a reservoir host of NiV, its large body mass (~700-900g) allows for relatively large volumes of blood and lymphoid cells to be safely sampled to support clinical research, its conservation status is "non-threatened" (thus allowing wild founders to be more readily sourced), and it is easy to maintain and breed in captivity.

2) Who will establish the colony? Where would the bats come from and where would the colony be maintained?

Our group includes experts on the behavior and husbandry of bats, their ecology, the epidemiology of Nipah virus in wild populations, and the design and implementation of experiments involving non-traditional animal models.

Colorado State University is a registered NIAID contractor for establishing lab animal models and will be the location of the proposed bat colony. Tony Schountz, PhD is an Associate Professor in the Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine at CSU. Dr. Schountz previously established a breeding colony of, Jamaican fruit bats *(Artibeus jamicensis)* that has been used for Tacaribe virus and MERS-CoV experimental research. CSU currently has the facilities to establish a colony of *Pteropus medius* and Dr. Schountz and Richard Bowen, DVM, PhD will be responsible for establishing and maintaining the research colony. The Director of Laboratory Animal Services at CSU is Lon Kendall, DVM, PhD, who has overseen the veterinary care of the Jamaican fruit bat colony. Thus, the facilities and staffing expertise are already in place at CSU for working with bat colonies.

Draft: Pre-White paper for discussion
Epstein et al. 2016

Dr. Jonathan Epstein, a veterinary epidemiologist at EcoHealth Alliance, has nearly 20 years of experience working with pteropid fruit bats in the wild. His research has focused on the epidemiology and ecology of Nipah virus and other zoonotic agents in bats. He directed the capture, quarantine and transport of live *Pteropus vampyrus* from Malaysia (another reservoir of Nipah virus) to AAHL as part of an NIH-funded long-term study of henipaviruses in bats in 2005. He has been working in Bangladesh since 2006, and has established strong collaboration with the government of Bangladesh, including the federal wildlife authority. Dr. Epstein, and his team in Bangladesh will be responsible for the capture, quarantine, and transportation of the bats from Bangladesh to CSU (Fort Collins, Colorado). He will also provide guidance for the facility at CSU (e.g., diurnal cycles, feeding, enrichment, etc.). Dr. Epstein is currently collaborating with Drs. Schountz and Munster on bat immunology studies and will continue to provide leadership and scientific engagement in this and future collaborative studies related to bat immunology and virology related to the imported *Pteropus* bats.

Dr. Vincent Munster is a senior scientist in the Laboratory of Virology, Rocky Mountain Laboratories, NIAID, (Hamilton, MT). His work has focused on experimental studies of bat-borne high containment pathogens such as Ebola virus, Nipah virus, SARS-CoV and MERS-CoV. Dr. Munster will facilitate the establishment of the colony, and will be the laboratory lead and co-investigator on all experimental studies utilizing these bats. We will have the support and use of the BSL 4 laboratory and veterinary personnel at RML for experimental work utilizing the bats.

Mr. Brian Pope, the Director of the Lubee Bat Conservancy in Gainesville Florida has more than 12 years of bat husbandry experience at zoological parks, including Disney World's Animal Kingdom, and will provide expert guidance on the regulatory aspects of bat importation and the development of the internal environment for the bat colony. He and his staff will provide training to the veterinary and animal care staff at CSU and RML on the husbandry and care of the bats. Mr. Pope and Dr. Epstein have collaborated for more than five years on bat immunology studies at the Lubee Bat Conservancy, and Dr. Epstein currently serves on Lubee's Scientific Advisory Board.

To found the colony, we propose to import 40 adult *P. medius* from Bangladesh, with the support of the Forestry Department – the federal wildlife agency. We will import 36 pregnant female bats, and 4 males - all seronegative for Nipah virus. A temporary quarantine facility will be constructed by the Forest Department at the Dhaka zoo, where veterinary and animal care staff are available. Bats will be sampled (blood and urine) every three weeks and samples will be sent to RML laboratories and tested for Nipah virus antibodies and RNA using ELISA, SNT, and PCR.. Bats that have three consecutive negative tests will be shipped to CSU. Our group previously transported pteropid bats from Malaysia to Australia for research purposes. *P. medius* is a seasonal breeder, and females within a colony tend to be pregnant all at once, so capturing 35 pregnant females is achievable. The gestation period is six months, and the timing of transport will be such that the bats will be in the fourth month of pregnancy to maximize the safety to the fetus during transport. We expect 80-90% of pregnancies to be maintained during quarantine and shipment, such that the colony will immediately provide about 30 juveniles that could be used for experimental work within 12 months of birth or to continue breeding after 30 months when they reach sexual maturity. The adults will be bred every year (one breeding cycle per year), which will generate a cohort of 20-35 bats each season. Over a period of 3-5 years, we expect to have generated a colony of more than 200 bats that will be available for experimental studies.

3) Long-term sustainability.

Use of the bat colony as well as cell lines derived from bat tissues will be made available to the scientific community. We expect that cell lines will be the most frequently requested products that could be readily shared among the scientific community. Have a supply of primary and immortalized (e.g., large T, hTERT) cell lines in the US will rapidly facilitate research because it will obviate the need for CITES and other import permits when reagents are shipped to other US-based labs. The colony will also benefit conservation efforts by providing genetic material to zoological institutions that have breeding programs for *P. medius* now or in the future.

Support from NIAID will be required to establish and expand the colony over an initial 5-year period. Once the colony is established, we will generate reagents and cell lines that will be made available to other researchers upon request. After the completion of the contract and to support the maintenance of the colony and associated resources, we will establish a modest fee structure for use of the bats and materials derived from the bats, which will be channeled directly back into colony maintenance costs. We will also consider experiments that require the use of bats and will include budget in each proposal that will be used to support maintenance costs. The fee structure could be modeled from the one used by the Lubee Bat Conservancy, or a de novo fee-for-service system will be developed.

Critical research to understand emerging zoonotic viruses requires a US-based captive bat colony

Prepared by Jonathan Epstein, DVM MPH; Tony Schountz, PhD; Judith Mandl, PhD; Richard Bowen, DVM, and Vincent Munster, DVM, PhD.

There is a growing consensus among the scientific community studying high consequence zoonotic viruses, that in order to understand why these viruses are lethal in people it is necessary not only to study their basic structure and function; their pathogenesis; their epidemiology and host ecology; but it is also vital to understand how these viruses behave in their hosts, which appear to be infected without signs of clinical disease. Of particular concern to the global health community are a suite of zoonotic viruses that cause high mortality in people and that are believed to originate in bats: SARS coronavirus, Ebola virus, Marburg virus, Nipah virus, Hendra virus, and Middle East respiratory syndrome coronavirus (MERS CoV). Further, there is increasing evidence that groups of established human pathogens originated in bats, including measles, mumps, hepatitis C virus, and potentially influenza viruses. An important and frequently asked scientific question is whether bats are better hosts for lethal viruses than other mammals. A bat animal model that can be used in controlled experiments is essential for developing a better understanding of basic bat immunology and will allow for sophisticated viral infection studies which may ultimately answer this question and lead to new approaches in antiviral therapeutics for people affected by diseases like Ebola virus disease, Nipah virus encephalitis, and Marburg Hemorrhagic fever.

We propose to establish a sustainable, *Pteropus giganteus* colony in the United States that will allow research requiring bats and bat-derived reagents such as cell lines to be conducted. We propose *Pteropus giganteus* as a model species because it is the natural reservoir for Nipah virus in South Asia, a virus with pandemic potential that causes near-annual outbreaks of fatal encephalitis in humans in Bangladesh with case fatality rates averaging 75% and that have reached 100%. Nipah virus is categorized as a category C select agent and biosafety level 4 pathogen. *Pteropus giganteus* is also host to more than 50 other viruses that have been identified (Anthony S, Epstein JH, et al., *mBio* 2013). Serological evidence suggests it also carries a yet unidentified filovirus (Epstein et al., unpublished). This species is robust and easily adapted to captivity compared to other bat species. Our group has extensive expertise with pteropid bat husbandry; experimental studies of Nipah virus and other BSL 4 viral pathogens, and studying viral epizootiology and bat ecology in wild populations in Asia. We have access to founder bats and facilities where a colony could be established and sustainably maintained (Colorado State University) and where research on select agents and high consequence viral pathogens could be conducted (NIH Rocky Mountain Laboratories).

The following is a list of research questions and ideas we have developed to illustrate the need for establishing a colony of *Pteropus giganteus* at a qualified research institute in the United States.

***In vivo* studies: Functional bat immunology / physiology / viral evolution**

- Characterizing the innate immune system of pteropid bats. This requires access to primary cells and hence a live, infection-free, colony from which, for example, blood can be taken on a regular basis for *in vitro* testing. A live colony will also allow controlled *in vivo* experiments where their innate immune response can be interrogated using the administration of defined stimuli that have been used in humans, primates, and mice.

- Characterizing the innate and adaptive immune response of pteropid bats to infection with viruses for which they are known reservoirs. A key question remains whether bats develop significant pathology from infection with the viruses for which they are natural hosts. It has been hypothesized that bats are distinct from humans in specific immune pathways as a result of having evolved to fly and hence having adapted to repair DNA damage that is the result of acute oxidative stress and inflammation caused by flight. This research was done using pteropid bat cell lines in Australia. A live *Pteropus* colony will enable us to determine whether pathology occurs following infection with Nipah virus, and whether reduced/absence of disease is also seen with other RNA viruses that are harbored by other bat species (eg. Ebola, MERS Cov). Experiments in controlled conditions will also enable us to address whether there are indeed aspects of bat physiology which impact their immune response as a result of their ability to fly. It will also be important to compare the components of the bat innate immune response to viral infection with an agent originating in pteropid and non-pteropid bats (Ebola virus, Nipah virus, Marburg virus, SARS CoV) to viral infection with a non-bat virus (e.g. Rift Valley Fever virus, HPAI H5N1 influenza virus, etc…).

- Kinetics of antibody production in NIPV-infected *P. giganteus*. When do IgM and IgG appear? When does neutralizing antibody appear? How long do neutralizing and non-neutralizing (e.g., N protein) persist?

- Lymphocyte responses during infection. What are the temporal and kinetic transcriptional profiles of *P. giganteus* lymphoid responses? RNA-Seq and qPCR could be used here.

- What occurs in immunosuppressed *P. giganteus* infected with NiV?

- Do bats get sick from the above viral infections? A bat model is necessary to determine the pathology that occurs during infection and whether clinical signs occur that would allow one to observe disease in bats. Pathogens of high importance include Nipah virus, Ebola, MERS CoV. Can we appreciate clinical

signs when bats have been infected with viruses associated with different but related bat hosts? For example, what if one pteropid species infects another pteropid species with its particular henipavirus? What clinical signs can be observed in the recipient host? What mutations occur in the viral genome following interspecific transmission? What about transmission to another bat species within the same family (e..g from *Pteropus giganteus* to *Rousettus aegyptiacus.*) In nature, multiple species often share habitat and may exchange viruses, assisting in viral persistence in a geographic area. **This would help understand viral evolution when multiple hosts are involved – as is the case with Nipah virus in Southeast Asia, Hendra virus in Australia, and Ebola virus in Central Africa**)

- Characterizing the complete genome of *Pteropus* with >50x coverage to look at the presence/absence and actual nucleotide sequences of genes responsible for innate immune function. Comparison to other species (particularly humans) will enable probing for different types of selection pressures, which may provide clues as to which genes have changed due to specific adaptations (positive selection) versus which genes have been under strong selection pressure to remain conserved to maintain their function.

- What mutations occur following conspecific bat to bat transmission of Nipah virus?

Specific viral pathogen research: Henipaviruses (Nipah virus, Hendra virus, Cedar virus); Filoviruses (Zaire ebolavirus, Marburg virus, Reston ebolavirus); and Coronaviruses (SARS and MERS).

- Characterizing Nipah virus transmission and replication in pteropid bats. Controlled experiments where the dose, route and time of virus exposure is precisely known will enable us to determine: by what route virus shed, what the extent is of viral replication (timing, magnitude) in different tissues, what the timing and magnitude is of viral shedding. Answering such questions will be essential to determining how Nipah virus is transmitted between bats and how Nipah virus is transmitted from bats to other animals. It will also reveal what the highest risk tissues are for transmission to humans, e.g. during butchering, whether virus can be transmitted through blood contact, through urine/feces, etc.

- How does Nipah virus infection / transmission differ from other henipaviruses like Hendra and Cedar virus? Can differences in pathogenesis among these viruses provide insight into immunity and potential therapeutic approaches? How do henipavirus infections compare to filovirus and coronavirus infections?

- Are there molecules or compound in existing libraries that can block or limit Nipah virus shedding/transmission in host species? How do these mechanisms

work? Could this be applied to other animal models and ultimately used to reduce viremia in people?

- What are the highest risk tissues in bats that may results in Ebola transmission during butchering? What are the peak viremic levels during acute Ebola infection? Nipah virus? Could Nipah virus be transmitted to humans through contact with blood (e.g. during butchering process)?

- Are there mechanisms within the bat's innate immune system that can be mimicked by therapeutic agents to reduce pathology during human infection?

***In Vitro* Studies**

- A *Pteropus giganteus* colony will allow for the development of immortalized cell lines for use in *in vitro* experiments (these are a product from this colony that could be disseminated to other research groups in the United States to support research requiring bat cell lines).

- Are *P. giganteus* dendritic cells (pDC, cDC) and macrophages susceptible to NiV infection? How do the viral proteins affect the responses of these cells? A lot has been done in non-bat cells, but nothing has been done in *P. giganteus*. Are the STAT1 or MDA5 pathways similarly targeted in *P. giganteus* cells as they are in human cells?

- Are *P. giganteus* endothelial cells susceptible to NiV? If so, how does the virus affect those cells (e.g., lytic, non-lytic, suppression of type I/III IFN pathways)?

- Are infected *P. giganteus* cells susceptible to CTL-mediated lysis?

- What are the profiles of helper T cells from NIPV-infected bats?

- Are there commercially available antibodies that are cross-reactive with *P. giganteus* proteins? Many of the antiviral protein Abs should be cross reactive, but less so for cell surface proteins or cytokines. We may find anti-CD4 and anti-CD8, which could lead to depletion studies *in vivo*.

Ultimately, such studies will collectively reveal whether there mechanisms within the bat's innate or adaptive immune system that can be mimicked by therapeutic agents to reduce pathology during human infection with zoonotic viruses originating from bat species.

Subject: Bat space at CSU

Hi Jon,

Here's what we know about our "barn" space, per Lon Kendall, our lab vet here at CSU, and someone I very much trust. Pasted from various emails that have been flying around today:

If it is the Pteropus, a renovated barn could hold approximately 25 bats. Maybe good for some short term studies, but insufficient for a breeding colony.

There is not an existing building that would meet the space requirements of the Pteropus. The barn is about 2500 sf, and we would need 7500 sf for a 60 bat breeding colony, plus support space, so about 10000 sf. I can't think of another space that large that could be renovated.

This puts us in a position where we're seeking funds to construct/add on to a facility *in order to be able to apply for funds to renovate that facility*. I think this is more than I can ask, and think our best course is to move on. I'll reach out one last time to our NIH contacts, but this seems like a dead end to me if the really can't find a way to fund the C06 (which seems very off to me – if they want to fund it they should be able to do so in my opinion).

Sorry not to have better news.

Greg

Subject: Bat tissue

Tony,
I just heard that Lubee's P. giganteus recently died and I think they've harvested tissue. Were you aware? Did you get any samples?
-Jon

Subject: C06 check in call

Hi all,

Here is the zoom invitation for the call to discuss the status of the CSU C06 proposal. The meeting is Thursday, 28-May at 2:00 Mountain, 4:00 eastern.

Best,

Greg

Gregory Ebel is inviting you to a scheduled Zoom meeting.

Topic: C06 Check In
Time: May 28, 2020 02:00 PM Mountain Time (US and Canada)

Subject: C06 update documents
Attachment(s): "C06 Update 2020_clean.docx","Munster LoS_Ebel_signed.pdf"

Dear Jean and Mark,

As promised, I'm attaching a two page update on the C06.

It highlights (a) the overall rationale for the project, (b) our vision for how it would be used, and (c) a summary of current bat-focused experimental research that it would support.

The overall picture that I would like to convey is that CSU is an ideal environment for locating a bat facility due to our longstanding interest in emerging zoonotic and vector-borne infections and our commitment to developing infrastructure to support research in this area. I very much hope that this comes through. If you think that there are points that are being missed, please let me know and I can edit further.

I'm also attaching a letter of support from Dr. Vincent Munster at RML. If you think it would be helpful in moving this forward, we can also obtain a letter from EcoHealth alliance supporting the project.

Thanks so much for your attention and do let me know how I can further help move this project forward.

Best regards,

Greg

Pathogens transmitted by bat and arthropod vectors continue to significantly threaten the health of humans and domestic animals around the world. Bat-associated pathogens, such as coronaviruses, including the currently circulating SARS-CoV-2; filoviruses (e.g. Ebola and Marburg viruses), and henipaviruses (e.g. Nipah virus), are among the most impactful and dreaded viruses known. Malaria is perhaps the most deadly infection in the tropics. West Nile, chikungunya and Zika viruses also have emerged as major global pathogens. Tick-transmitted infections such as Lyme disease and Powassan virus continue to emerge in temperate regions as climate change expands the range tick vectors. Agents hosted by bats and vector-borne pathogens thus constitute some of the most feared, difficult and persistent problems affecting human health.

To meet this challenge, Colorado State University (CSU) established the Arthropod-borne and Infectious Disease Laboratory (AIDL) in 1984 to counter these emerging threats. One of the many unique aspects of AIDL includes housing one of the only captive breeding colonies of bats for use in infectious disease research. One of the major challenges for studying the origins, transmissibility and pathogenesis of emerging bat-borne viruses is the lack of bat animal models. The species diversity of bats is second only to rodents among mammals, however, there are key species that have been associated with important groups of zoonotic viruses such as Ebola and Marburg virus, Nipah virus, and SARS and SARS-CoV2-related coronaviruses, and there is growing evidence that bats are physiologically and immunologically unique in their ability to tolerate viral infection, resist cancer, and have disproportionately long lifespans for their size. All of this makes the dearth of facilities capable of housing bats for basic research and the lack of available bat colonies in the United States for use in biomedical investigations a major impediment to basic infectious disease and translational medicine research. The current COVID-19 pandemic highlights the national need for the proposed facility as a scientific resource, and the central role that CSU now occupies in the ability of the US to study and design countermeasures against emerging viral threats.

To support research into significant known and unknown emerging diseases, including those listed by the WHO R&D Blueprint as the ten most significant infectious disease threats to global health (half of which are bat-associated or vector borne viruses), CSU committed $22M in 2019 to construct a new building, the Center for Vector-Borne Infectious Diseases (CVID), to replace aging AIDL infrastructure. CVID construction is ongoing and we anticipate moving in in late 2020.

While CSU's commitment of $22M is laudable, it has proven insufficient to provide adequate housing for the additional bat colonies needed to address the urgent need for research into the biology and emergence of SARS-CoV-2, MERS CoV, Nipah virus, Ebola and yet-to-be discovered viral agents which are most likely to emerge from bat reservoirs. Further, additional infrastructure within the CVID is required in order to ensure that research focusing on bat-borne diseases is paired with adequate BSL2 and BSL-3 lab, tissue culture and other support space.

This proposal, which scored well in 2019 but was not selected for funding, represents a unique opportunity to rapidly accelerate US capacity for housing, breeding and using bats in biomedical research. In particular, we propose to:

- **Develop a state-of-the art facility to house a breeding colony of *Pteropus* fruit bats** known to be natural reservoirs for henipaviruses, filoviruses, and coronaviruses. This will be the first of its kind in the world, and will be a critically important resource for:
    - **Developing and generating reagents** including cell lines, validated serology and PCR assays, etc.

- **Studying basic genomics.** Groundbreaking work has begun in Singapore and Australia on bat viral tolerance using an Australian *Pteropus* species. The proposed facility will allow the US to actively accelerate this area of research by focusing on a natural reservoir for Nipah virus, filoviruses, and coronaviruses.
- **Build on the existing immunology and genomics work, and develop new lines of cancer and aging related research** by engaging investigators from various centers at NIH, CSU, EcoHealth Alliance, and around the world.
- **Experimental work involving high containment pathogens** (Nipah virus, Ebola, etc..) will be conducted through a partnership with EcoHealth Alliance, and NIAID Rocky Mountain Labs (see Munster letter of support) in Hamilton, MT.

- **Develop facilities to permit the importation of other key bat species** (e.g. *Rhinlophus affinis*) and house native North American bat species for use in coronavirus research, including SARS CoV-2 within CVID.

Current Bat Research at CSU

Colorado State University has a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*), one of the most common and largest fruit bats in the New World. This colony was established in 2005 with funds from the NIAID Emerging Virus Disease Unit contract (AI25489) after it was determined that SARS-CoV was a bat-borne virus. Currently funded bat projects are to study SARS-CoV (CSU VPR funding), MERS-CoV (AI140442), bat influenza A viruses (AI134768), henipaviruses (DARPA G228-19-W7329) and rabies virus (DOE B634747). Our long-term goal for this colony is to make it the “bat version” of the laboratory mouse so that we can conduct experimental infections for other researchers, or provide bats to those who may need them for experiments at their institutions.

Our progress with these bats thus far has been remarkable. We have determined they are susceptible to several viruses, including Zika virus, H18N11 bat influenza A virus, MERS-CoV, Cedar henipavirus, Tacaribe virus and Bukakata virus, the last two of which cause fatal diseases in the bats. We also have established primary bat cell lines that are susceptible to MERS-CoV, Zaire ebolavirus, and Nipah, Hendra and Cedar henipaviruses. We have generated a number of reagents, including monoclonal antibodies and recombinant cytokines, virological and immunological methods, large transcriptome data sets, basic physiological parameters. Our work has demonstrated that it can serve as a surrogate bat model organism for the study of bat-borne viruses. Importantly, a genome assembly to 30x coverage is available (NCBI PVKR01). These bats already have been used to address SARS-CoV-2 infection. We performed an initial susceptibility study of three Jamaican fruit bats and found that all had low levels of viral RNA in oral swabs within a few days after intranasal inoculation. By day 14, all three bats had seroconverted by ELISA to recombinant SARS-CoV-2 nucleoprotein and by day 24 the titers had increased at least 4-fold for each bat, with titers up to 1:6400. Thus we are confident that we have established a surrogate bat model for the study of SARS-CoV-2 in bats. We currently have 27 bats enrolled in a challenge and transmission study and are performing serial euthanasia to determine virus kinetics, tissue tropism, host response and transmission dynamics. Our productivity with our existing bats, and committed partnerships with Rocky Mountain Labs and EcoHealth Alliance who are invested in emerging disease research, clearly demonstrates their importance as research resources and our ability to productively engage with a wide array of projects and partners, indicating the suitability of CSU as a home for new bat housing and laboratory support facilities.

April 1st, 2020

Dear Dr. Auchincloss,

It is with utmost pleasure to be able to provide a letter of support for the CSU bat research center. Past outbreaks of bat-borne zoonotic viruses such as coronaviruses, henipaviruses and filoviruses, have had an enormous impact on human and wildlife health. The unpredictability of the zoonotic introductions of these bat-borne limits the potential for effective intervention strategies. Within my research at the NIAIDs Rocky Mountain Laboratories, I have directly focussed on bat-borne viruses such as Nipah virus, Ebola virus, MERS-CoV and now SARS-CoV-2. In particular we have extensive knowledge of bat infection models of ß-coronaviruses (MERS-CoV and WIV-1, in *Artibeus* and *Rousettus* bats) and Nipah virus (*Rousettus* bats) and are one of the few facilities which are completely set-up to perform bat studies in high and maximum containment (including long-term husbandry and on-site veterinary staff) and complete downstream immunological, genetic and virological analyses. In the absence of suitable breeding facilities at intramural NIAID, the addition of a centre focussed on *in vivo* bat research at CSU deserves the NIAIDs unconditional support.

I am underwriting my enthusiasm to continue to collaborate on the development of a bat resource center including breeding colonies of key bat species, at CSU. Having access to natural hosts for coronaviruses, henipaviruses and filoviruses would significantly advance research in infectious disease undertaken by my group and others at RML, and I am committed to working with Drs. Bowen and Schountz at CSU (long standing research collaboration on MERS-CoV) and Dr. Epstein of EcoHealth Alliance (long standing collaboration on the underlying ecological changes driving spillover events of Nipah virus) to develop and use the resources generated through this C06 proposal. The SARS-CoV-2 pandemic marks an occasion which should put renewed focus on detailed studies of bats as reservoirs of emerging diseases. After SARS-CoV-1, MERS-CoV and Ebola virus in West Africa, we have yet another high impact (both from public health as economic perspective) bat-borne disease which justifies the urgent need for facilities in the US for advanced bat infectious disease studies.

Please feel free to contact me with any remaining questions,

Sincerely,

Vincent Munster

Subject: Could you please fill in this questionnaire concerning bat conservation in China?

Dear Bat Researchers,

Good day! More than 130 bat species have been recorded in China. None of them are included in the List of Chinese State Key Protected Wildlife, although some bat species are in rapid decline in recent decades. Many Chinese people experience intense panic at the thought of bats and some even propose to kill bats since the outbreak of novel coronavirus (COVID-19). In this case, we are dedicated to gathering researchers' opinions on the major threats and conservation strategies of bats in China. We restricted the population surveyed to researchers and students worldwide that have research experience on bats. Through this brief survey, your answers may be helpful in improving the conservation status of bats in China. There is no right or wrong answer to the question. Your response will only be used for survey purposes. Thank you very much for your valuable time and suggestions! Could you please also send this email to your colleagues and students?

Here is the network link of our self-designed questionnaire: https://www.wjx.cn/jq/66714439.aspx

Subject: CSU Bat space

Dear Jean,

I'm writing to let you know that as of this AM, we are seeing some traction toward renovation funds for a bat facility at CSU. I think it makes sense to discuss next steps as long as interest remains at NIAID in moving forward with this effort.

Thank you,

Greg

EcoHealth Alliance

EcoHealthNet 2019

EcoHealthNet (EHN) is an undergraduate and graduate-level global research coordination network, funded by the National Science Foundation, to bring together world-class research scientists from medical, ecology, veterinary, epidemiology, virology, anthropology, climate science, data science, and economics that will advance One Health research and education. Advancements will take place through three activities: 1) create a peer network of undergraduate and graduate STEM students from various disciplines via 1-week workshops that teach applied skills and provide in-person contact time with scientists actively conducting research related to anthropogenic environmental change, economics, and emerging diseases, which will also be delivered live as an interactive webinar to university students globally; 2) develop the next generation of One Health practitioners through mentored research projects that reflect One Health principles; 3) link participants to professional science and policy associations. This project will develop and deliver live online content to thousands of students on a global scale. This project will inspire broad, One Health research, which will create lasting connectivity among scientists from different disciplines as they advance in their careers.

The online application for 2019 are now open until December 31st!

The 2019 Workshop, **Emerging Threats to Global Health**, will be held at George Mason University in Virginia from June 2-8th, in collaboration with Johns Hopkins University and the Smithsonian Institute. Research Exchange projects can take place between May and August 2019.

EcoHealthNet is made possible through a partnership among EcoHealth Alliance, Harvard School of Public Health, Tufts University, University of California - Davis, Chittagong Veterinary and Animal Sciences University of Bangladesh, George Mason University, Columbia University, Johns Hopkins B SPH, Agriculture and Forest University of Nepal, University of Wyoming, Royal Veterinary College, London, University of Wisconsin Madison, Wuhan Institute of Virology China, National Wildlife Health Center, Universidad National Autonoma de Mexico, Chulalongkorn University Thailand, University of Georgia, and a number of other partners.

Hi Greg,
We are all hanging in here, just working! Hope you are doing well too.
I don't have confirmation yet as to whether the C06 will get picked up. I will say that Mark and I have been thinking of a Plan B just in case and at some point soon plan to set up a call with you all to discuss further.
Sorry I don't have better news, but will explain when we get on a call.
Be in touch!
Jean

Subject: C06 check in

Hi Jean,

Just wanting to check in on the C06 progress.

Hope things are going well for you and that you're staying safe.

Greg Ebel

6 reasons why bats aren't enemies: They help make tequila, and other surprising facts you may not know

By Kristen Rogers, CNN

Updated 5:59 AM ET, Sun June 14, 2020

(CNN) Bats have shouldered much of the blame in the quest for the origins of the novel coronavirus.

In March, researchers published a study that found a 96.2% similarity between the

coronavirus that causes Covid-19 and a virus found in a horseshoe bat from China's Yunnan province.

"Ninety-six percent is a different virus; it's a bit like the difference between us and chimpanzees," Peter Daszak, the president of the non-profit EcoHealth Alliance, explains in CNN Special Report "Bats: The Mystery Behind Covid-19."

"It's a different species of virus. But what it tells us is where the virus probably came from. It means that SARS-CoV-2 probably came from bats and probably in Southern China."

Yunnan province is about a thousand miles from Hubei province, which is where the city of Wuhan saw the early virus outbreaks. A mix of potentially infected wild animals in a wet market could have caused the virus to jump from animals to humans. But zoologists, ecologists and disease experts have said that it's human behaviors — such as destroying natural habitats — that might be to blame for the transfer of the disease.

Overall, bats have caught a bad rap — not only with their connection to Covid-19 and other virus outbreaks but in cultural symbolism as well. Bats have been associated with vampires, darkness, evil, witchcraft and death.

However, as experts tell Anderson Cooper in the CNN special report, these flying mammals have a crucial role in our ecosystem, and there are many unique facts that the average person likely doesn't know about them — including how they help produce tequila.

They save us from mosquitoes

Bats play a large role in the ecosystem by controlling insect populations, said Nancy Simmons, American Museum of Natural History mammalogy curator and coauthor of "Bats:

A World of Science and Mystery."

Newly discovered bats are related to those associated with the pandemic

In an hour, a normal-sized bat can eat up to 500 to 1,000 mosquitoes, which can carry diseases such as the Zika virus, dengue fever or malaria.

Their insect-eating habits also save big money for agriculture. For the US economy, bats are worth over a billion dollars every year "in terms of how many pesticides we don't need to use and how much more food we get," said Dan Riskin, a Canadian evolutionary biologist and television host.

The Mexican free-tailed bat of Texas eats a great number of moths, protecting the corn crops of the region.

They're intrinsically environmentally conscious

Pest control isn't bats' only contribution to our ecosystem. The waste droppings of fruit-eating bats — particularly those in rainforests — disperse seeds, helping to regenerate plants and trees previously damaged or cut down.

Their droppings are also full of nitrogen, which is a vital ingredient for crops since it's a main component of chlorophyll, the compound by which plants use energy from the sun to produce sugars from water and carbon dioxide. This process, called photosynthesis, generates oxygen. Nitrogen is also a crucial element of amino acids, the building blocks of proteins.

And historically, bat caves have been harvested for fertilizer and then explosives during the Civil War. The high nitrate content of their feces provided a key ingredient for the production of gunpowder amid a shortage of supplies.

Cogs in the tequila-making machine

Some bat species serve as the only pollinators of particular types of bananas, mangoes and cacti. The muzzles of long-nosed bats are designed to fit perfectly inside some cactus blossoms, which fittingly only open at night.

This species, whose habitat ranges from the American Southwest to central and southern Mexico, pollinates the blue agave plant — the key ingredient in tequila. They act as surrogates carrying the pollen from one agave plant to another.

"Who doesn't love tequila, right?" Riskin said. "I mean, just right there, that should be reason enough for people to love bats."

They're fighting a disease humans gave them

While we're fighting a virus that potentially came from bats, they're fighting a fungus that might have transferred to them from us.

In North America over the past 15 years, populations of about a dozen bat species have been affected by a disease called "white nose syndrome." In some cases, populations have plummeted by more than 90%.

"It's a cold-loving fungus that grows on the bat when the bats are hibernating in the wintertime," Simmons said. "It's a terrible threat to bats. And ironically, it's a disease that we brought to bats. This disease is identical to fungus that naturally occurs in Europe. And so the thought is that it was simply brought over by people and was accidentally introduced into bat caves."

Lacking disease-related genes

When a virus infects our cells, our immune response will recruit immune cells to the site to

try to clear the infection, said Cara Brook, a postdoctoral Miller Fellow in the department of integrative biology at the University of California-Berkeley, in the CNN special.

The response that signals uninfected cells to turn on their defense system typically results in inflammation — which, in humans, is often in the form of fever or swelling that helps fight infection.

But bats' immune systems don't respond the same way — they're able to withstand strong immune reactions and have an anti-inflammatory response as well.

How vampire bats make friends before sharing meals of blood

Some bat species "are actually missing the genes that we and other animals have that trigger the inflammatory process" in response to pathogens and viruses that can be deadly for people and other animals, said Jonathan Epstein, a veterinarian, disease ecologist and the vice president of science and outreach at EcoHealth Alliance.

Studying bat immunology could help provide insights regarding possible treatments for the current pandemic, as well as any future pandemic of a bat-related virus.

Bats help pave the road to medical discoveries

Bats already contribute to research that could one day be helpful to humans.

In a 2019 study published in the journal Biology Letters, researchers analyzed evolutionary trees reconstructed from the DNA of the majority of known bat species. They found that four species — horseshoe, long-eared, common and mouse-eared — all live at least four times longer than other similarly-sized mammals.

And when adjusted for size, bats exceed the average human lifespan. The study added to previous research that suggested looking further into bats as models for healthy aging, to find traits and mechanisms associated with a long life span.

Vampire bats in particular — a rare species that lives in Central and South America and feeds on the blood of birds, pigs and cattle — have blood-thinning agents in their saliva, which helps them draw free-flowing blood from their prey. Scientists have looked into whether there are insights about their blood that would be helpful for treating humans.

Some studies have also suggested that vampire bats' blood might also lend to treatments for conditions including stroke, hypertension, heart failure and kidney diseases.

And now, studying how bats' immunology enables them to withstand numerous viruses and pathogens could be applied to developing prevention and treatment for humans.

Dear Zhengli,

I look forward to attending the October meeting in Wuhan organized by you (even though I have not got the official invitation.

In addition, I would suggest two more speakers for the meeting:
Dr. Chris Basler, Professor and Director of Emerging Viruses Center (?) at Georgia State University. Chris was at Mt Sinai School of Medicine and moved to Georgia. He is a world leader in Ebola virus research.

Dr. Balaji Manicassamy, Assistant Professor at University of Chicago. He attended the meeting two years ago, and his group works on influenza viruses. He has already contributed a lot to the field.

I may suggest one or two more if you like later.

Thank you for your great effort in organizing the meeting! We had a lot of fun last time.

Best regards,
Lijun

Subject: Your article has been published by Oxford University Press

Dear Author,

I am pleased to inform you that Oxford University Press has published your article in The Journal of Infectious Diseases.

Here are the links to your online article:

- Abstract: https://academic.oup.com/jid/advance-article-abstract/doi/10.1093/infdis/jiz648/5731483
- Article (free access): https://academic.oup.com/jid/advance-article/doi/10.1093/infdis/jiz648/5731483?guestAccessKey=9bcac963-434c-4c19-9a74-e1d7c153984d

These are persistent links that will always take you to your article, even if it is first published as an advance article ahead of being assigned to an issue.

Please see below for additional information and the conditions of use for links.

I trust that you have been perfectly satisfied with the service you have received. So that we can continue to improve, I should be very grateful if you would complete our questionnaire. There are only 6 short sections and it should take no more than 10 minutes to complete. Please click the following link or paste it into your web browser to access the questionnaire: http://www.surveymonkey.com/s/VBN7YSP

Thank you for publishing with Oxford University Press, and I hope to be of service to you again soon.

Best wishes,

Author Support Team
Oxford University Press

Additional information (please read)

Advantages of a free-access link to your article

There are several advantages to providing you with a free-access link to your article instead of a PDF file, including:

- Access to both the HTML and PDF versions of your article (where available).
- You (and your co-authors) will get free access to the final, published, and authoritative version of your article, which is available from our site whether or not you or they are a subscriber to the journal.
- We guarantee that you (and your co-authors) will have continued access to your article without the responsibility of maintaining and updating these files.
- All the linking and other functionality for your article remains in place.
- We can continue to gather accurate usage statistics for the journal to help us ensure that we continue to provide a good service for authors and readers.

Sharing the free-access article link with your co-authors

This email is only sent to the corresponding author of the article. You are free to share the free-access links with your co-authors and they are free to reuse the links according to the terms set out here. When sharing these links with co-authors, please share these terms and conditions at the same time.

Using the free-access article link

To access your article, click on the 'article (free access)' link above. If you reach a sign-in page, go back to this email and check if there are extra letters or numbers on the line below the URL. If so, the URL has broken over two or more lines and does not get picked up in its entirety by your browser when clicking through. In this case, copy and paste each line into the address bar of your web browser, deleting extra characters (such as < or >) or spaces. This should allow the URL to bypass subscriber sign-in.

Distribution of the free-access article link

You may distribute the free-access link to your article in the following ways:

- Single copies of the link may be shared with interested colleagues who wish to use the article for personal research/study purposes.
- The link may be posted to your personal/institutional website. However, the article should only be viewed from the Oxford Academic website and not posted to your own personal/institutional web site or that of other third parties.
- The link may be deposited into an institutional repository provided that it is not made publicly available until after the journal's embargo period, which can be found from the self-archiving policy link on the relevant journal site.

The free-access article link must not be distributed in the following ways:

- The link must not be shared on third-party commercial platforms.
- The link must not be shared via social media.
- The link must not be shared through subject-based repositories.

If you wish to reference your article on social media or through subject-based repositories, you are free to use the abstract link instead, if available.

Anyone wishing to make any other use of your article (e.g. commercial reuse) should contact journals.permissions@oup.com for permissions information or see thePublication rights policies webpage.

Advance articles and publication in an issue

The links provided in this email are persistent links that will always take you to your article, even if it is first published as an advance article ahead of being assigned to an issue. Once it has been assigned to a paginated issue, your article will acquire a volume, issue, and page reference. To be alerted when these details are available, please sign up for the journal's new issue alert.

Serological Evidence for Henipa-like and Filo-like Viruses in Trinidad Bats

Bat-borne zoonotic pathogens belonging to the family Paramxyoviridae, including Nipah and Hendra viruses, and the family Filoviridae, including Ebola and Marburg viruses, can cause severe disease and high mortality rates on spillover into human populations. Surveillance efforts for henipaviruses and filoviruses have been largely restricted to the Old World; however, recent studies suggest a potentially broader distribution for henipaviruses and filoviruses than previously recognized. In the current study, we screened for henipaviruses and filoviruses in New World bats collected across 4 locations in Trinidad near the coast of Venezuela. Bat tissue samples were screened using previously established reverse-transcription polymerase chain reaction assays. Serum were screened using a multiplex immunoassay to detect antibodies reactive with the envelope glycoprotein of viruses in the genus *Henipavirus* and the family Filoviridae. Serum samples were also screened by means of enzyme-linked immunosorbent assay for antibodies reactive with Nipah G and F glycoproteins. Of 84 serum samples, 28 were reactive with ≥1 henipavirus glycoprotein by ≥1 serological method, and 6 serum samples were reactive against ≥1 filovirus glycoproteins. These data provide evidence of potential circulation of viruses related to the henipaviruses and filoviruses in New World bats.

Keywords. Filovirus; Henipavirus; Trinidad; Bats; Screening; Serology; Luminex; RT-PCR

Since 1994, >350 human fatalities from Hendra (HeV) or Nipah virus (NiV) disease outbreaks have been reported [1–3]. Periodic outbreaks of Ebola and Marburg virus disease caused by members of the family Filoviridae have resulted in approximately 13 700 recorded human fatalities since 1976 [4, 5]. In addition to public health concerns, henipavirus and filovirus spillover events continue to have severe economic and ecological impacts [6–9]. Bats are natural reservoirs for some paramyxoviruses (NiV, Hendra virus, Cedar virus, Menangle virus, and Achimota virus 1 and 2) and some filoviruses (Marburg and Bombali viruses) and are the putative reservoirs for other paramyxovirus and filovirus species [10–21]. In the context of henipaviruses, the geographic distribution outside South and Southeast Asia, Africa, and Australia has yet to be determined [2, 22]. In the context of filoviruses, the broader ecology and circulation within their respective natural reservoirs and the extent of the geographic distribution of filoviruses are still largely unknown [23].

Henipaviruses have only been isolated from pteropid bats in Southeast Asia and Australia [13–15]. However, multiple studies have presented evidence for the presence of henipaviruses in Africa [16, 22, 24–30], with full genome sequences recovered for the bat-borne Ghana henipavirus in Ghana [18]. In addition, recent serological data suggest that African henipaviruses are capable of spillover into human and husbandry animal populations, although this data has not been associated with any recorded morbidity and mortality events [24, 28, 29]. A serological study by de Araujo et al found henipavirus-like antibodies in Brazilian bats. Given the distribution of bat species in Latin America that were serologically positive for the Brazilian henipa-like virus, it is possible that these viruses are circulating in Trinidad and Tobago.

The discovery of filoviruses outside Africa, including Reston virus (RESTV) in the Philippines, Lloviu virus (LLOV) in Spain, and Měnglà, Xīlǎng, and Huángjiāo viruses in China, demonstrates the broad geographic range of filoviruses [31–34]. Serological and polymerase chain reaction (PCR) evidence for filoviruses in China, Singapore, Bangladesh, and Hungary also suggest the possibility that uncharacterized filoviruses may circulate in bat populations beyond the currently described geographic range [35–39]. Han et al [40] used published filovirus surveillance data to predict bat species which may be potential filovirus reservoirs based on behavior, life history, and ecological traits; their study predicted that several New World bats,

Correspondence: Vincent J. Munster, National Institutes of Health, Hamilton, MT (Vincent.Munster@nih.gov).

The Journal of Infectious Diseases® 2019;XX:1–8

DOI: 10.1093/infdis/jiz648

including several bat species with populations in Trinidad and Tobago, may be potential hosts of uncharacterized filoviruses.

In 2012, bats of 6 species were captured from 4 locations in Trinidad. Malmlov et al [41] screened these bat samples and found evidence of the circulation of Tacaribe virus. We describe here the results of surveillance efforts for evidence of henipa-like and filo-like viral infection in the same sample set, because the breadth of the host range and geographic distribution are still largely unknown for these virus families.

METHODS

Ethics Statement

All field work was performed under the approval of the Ethics Committee, Faculty of Medical Sciences, The University of the West Indies (UWI), St Augustine Campus, and under a special game license from the Wildlife Section, Forestry Division, Ministry of Agriculture, Land and Fisheries, Republic of Trinidad and Tobago. All work with infectious henipaviruses and filoviruses was performed under biosafety level 4 conditions at the Rocky Mountain Laboratories, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, according to standard operating protocols approved by the Institutional Biosafety Committee.

Bat Capture

In February 2012, bats were captured with mist nets in Trinidad at 4 locations; Mount Hope (N 10.67120, W 061.28677), Lopinot (N 10.69792, W 061.32243), Santa Cruz (N 10.69596, W 061.44629), and Maracas Valley (N 10.70945, W 061.40177) (Figure 1). Cloth bags were used to individually confine and transport bats to laboratory facilities at the University of the West Indies, St Augustine for processing. Six bat species were obtained: 36 flat-faced fruit bats (*Artibeus planirostris trinitatis*), 31great fruit-eating bats (*Artibeus lituratus*), 3 Pallas's long-tongued bat (*Glossophaga soricina*), 7 greater sac-winged bats (*Sacropteryx bilineata*), 3 little yellow-shouldered bats (*Sturnira lilium*), and 4 Seba's short-tailed bats (*Carollia perspicillata*). Bats were euthanized through inhalation of isoflurane and exsanguination before necropsy. Tissue (lung, liver, kidney, spleen, brain, and blood) and serum samples were stored at −80° C before shipment on dry ice to Rocky Mountain Laboratories for further processing.

Luminex Serology

The presence of immunoglobulins against henipavirus- and filovirus-soluble native-like oligomeric virus envelope glycoproteins was measured using a Luminex xMAP-based multiplex microsphere immunoassay (MIA) [37, 42]. Briefly, soluble tetrameric henipavirus receptor binding proteins (sG_{tet}) (Yan et al in review) and soluble trimeric ectodomains of filovirus envelope glycoproteins were produced, as described elsewhere [37]. Purified $sG_{tet}$and envelope glycoprotein antigens were coupled to Bio-Plex Pro magnetic COOH beads (Bio-Rad). Blood was collected into serum separating tubes by means of cardiac puncture with bats under deep anesthesia, and it was centrifuged at 1000*g* for 10 minutes before serum was collected and frozen at −80°C. We performed the Luminex assay on serial dilutions of negative control serum samples from 14 captive-bred *Rousettus aegyptiacus* bats to determine an appropriate dilution for screening bat serum samples with the Luminex assay. All negative control serum samples were negative at a final dilution of 1:500. Field-collected bat serum samples were heat inactivated at 56°C for 30 minutes and diluted 1:500 before screening, and each sample was run in duplicate.

Enzyme-Linked Immunosorbent Assay

Nunc Maxisorp 96-well flat-bottom Immuno Plates (ThermoFisher) were coated with purified Nipah F and G glycoproteins (50 ng in 100 µL per well, diluted in phosphate-buffered saline [PBS]) overnight at 4°C. Plates were washed 3 times with PBS with 0.1% Tween 20 (PBS-T) and then blocked with 5% nonfat milk in PBS-T (100 µL per well) for 1 hour at room temperature. After being washed 3 times with PBS-T, diluted bat serum samples (1:100, 1:250, or 1:500 in 5% nonfat milk) were added to the wells in duplicate (100 µL) and incubated for 1 hour at room temperature. Plates were washed 5 times with PBS-T. Secondary antibody (goat anti-bat immunoglobulin G [IgG; heavy and light] horseradish peroxidase conjugate; Bethyl; 1:2500) was added to wells (100 µL) and incubated for 1 hour at room temperature. After 5 washes with PBS-T, 100 µL of a 1:1 ratio of 3,3',5,5'-tetramethylbenzidine (TMB) solution and peroxide solution (Pierce TMB Substrate Kit; ThermoFisher) was added to wells. Plates were allowed to develop in the dark. After stopping the reaction with 100 µL of 2 mol/L sulfuric acid, plates were read at 450 nm.

In Vitro Transcription

Bombali virus and LLOV have not been isolated. Therefore, in vitro transcripts were generated as positive controls. RNA-dependent RNA polymerase coding sequence segments of Bombali virus and LLOV were synthesized into pUC57 cloning vectors (Biobasic). Plasmids were transformed into Stellar Competent Cells, following protocol PT5055-2 (Clontech). Plasmids were isolated using a PureLink HiPure Plasmid Midiprep kit (Invitrogen). Linear templates were generated by a single digestion with restriction enzyme EcoR1, according to the manufacturer's protocol (New England Biolabs). Negative-sense RNA was transcribed using the MEGAscript T7 kit.

Nucleic Acid Extraction

RNA and DNA from Trinidad bat tissues were extracted using the Cador Pathogen 96 QIAcube HT Kit and QIAcube robot (Qiagen). The bat tissues were lysed in RLT buffer (Qiagen), followed by incubation in 95%–100% ethanol for 10 minutes before extraction. Extracted RNA from virus stocks of all currently

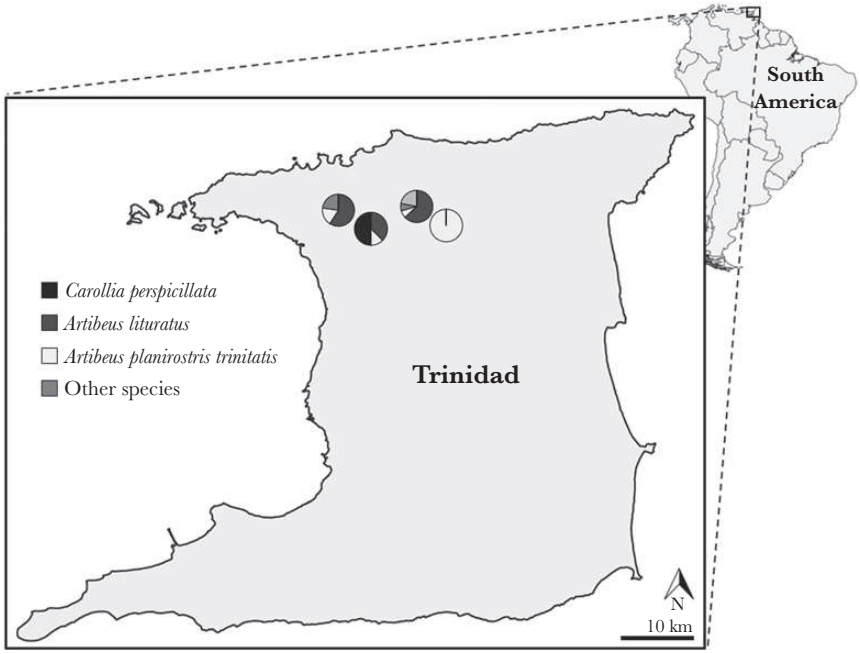

Figure 1. Field sites of bat capture. Collections at Mt Hope were performed during the day at the University of West Indies. Collections at Santa Cruz, Maracas Valley, and Lopinot were performed over 3 nights.

isolated henipavirus and filovirus species were used for assay validation and positive controls. RNA was isolated using the QIAmp Viral RNA Kit (Qiagen) in a biosafety level 4 laboratory, with published modifications appropriate for virus inactivation in biosafety level 4 conditions [43]. Henipaviruses included were NiV, species *Nipah henipavirus*, isolate Malaysia; HeV, species *Hendra henipavirus*, isolate Hendra; and Cedar virus (CedV), species *Cedar henipavirus*, isolate Cedar. Filoviruses included were Ebola virus (EBOV), species *Zaire ebolavirus*, isolate Gabon; Sudan virus (SUDV), species *Sudan ebolavirus*, isolate Boniface; Taï Forest virus (TAFV), species *Taï Forest ebolavirus*, isolate Taï Forest; RESTV, species *Reston ebolavirus*, isolate Pennsylvania; Bundibugyo virus (BDBV), species *Bundibugyo ebolavirus*, isolate Bundibugyo; Marburg virus (MARV), species *Marburg marburgvirus*, isolate Angola; and Ravn virus (RAVV), species *Marburg marburgvirus*, isolate Ravn.

Henipavirus, Morbillivirus, and Respirovirus Assay

Complementary DNA (cDNA) was synthesized from 10 µL of RNA using the SuperScript III or IV First-Strand Synthesis System for reverse-transcription PCR (RT-PCR) (Invitrogen). RT-PCR was performed using TopTaq Master Mix Kit (Qiagen) 50-µL reactions, with 25 µL of TopTaq MasterMix, 5 µL of CoraLoad Dye, 1 µL of 10 µmol/L primers (final concentration 1.0 µmol/L), and 5 µL of cDNA template used for each reaction. Previously designed primers targeting a conserved region of the RNA-dependent RNA polymerase gene for henipaviruses, morbilliviruses, and respiroviruses [44] were used for PCR. Thermal cycling conditions were followed, according to the manufacturer's protocol, with an annealing temperature of 50°C. PCR products were analyzed using a 1% agarose gel and SYBR Safe DNA Gel Stain (Fisher Scientific). The expected fragment size based on the position of the second primer set was approximately 600 base pairs.

Panfilovirus Assay

cDNA was synthesized as described above. Nested RT-PCR was performed using TopTaq Master Mix Kit (Qiagen) 50-µL reactions, including 25 µL of TopTaq MasterMix, 5 µL of CoraLoad Dye, 1 µL of 10 µmol/L primers (final concentration 0.2 µmol/L), and 5 µL of cDNA template for each reaction. Previously designed primers targeting a conserved region of the filovirus RNA-dependent RNA polymerase gene [19] was used for nested PCR, with the addition of a modified forward primer for the second reaction (5'-TYTCHVT/ideoxyI/CAAAA/ideoxyI/CAYTGGGG-3'). Thermal cycling conditions for both rounds were as follows: 94°C for 5 minutes; 15 cycles of 94°C, 60.9°C (−1°C/cycle), and 72°C for 1 minute each; 15 cycles of 94°C, 45.9 °C, and 72°C for 1 minute each; and a final extension at 72 °C for 7 minutes. PCR products were analyzed using a 1% agarose gel and GelRed Nucleic Acid Stain (Phenix Research Products) or SYBR Safe DNA Gel Stain (Fisher Scientific). The expected fragment size based on the position of the second primer set was approximately 680 base pairs.

RT-PCR Limit of Detection

The genome copy number from the respective henipavirus and filovirus controls was determined using a 1-step protocol

for Droplet Digital PCR (ddPCR) and the Automated Droplet Generator (Bio-Rad), according to the manufacturer's instructions. Eight representative filoviruses (Supplementary Figure 1) and 3 representative henipaviruses (NiV, HeV, and CedV) were used to determine the limit of detection (LOD) for the RT-PCR assay with ddPCR before bat screening. Primers and probes used are listed in Supplementary Table 1. The LOD was determined by means of serial 10-fold dilution of viral RNA–positive controls and further refined with serial 2-fold dilution. The LOD was determined based on the highest dilution from which an observable PCR product was obtained.

RESULTS

Serum samples from 84 Trinidad bats were screened with MIA for the presence of antibodies reactive to henipavirus or filovirus envelope glycoproteins. The median fluorescence intensity (MFI) cutoff value was set as 3 times the mean MFIs of a naive serum sample from a captive Egyptian fruit bat (*R. aegyptiacus)*. The percentage of bat serum samples reactive against henipavirus- or filovirus-soluble glycoproteins was 3.57% (3 of 84) and 7.14% (6 of 84), respectively. Six serum samples from *A. lituratus* bats were reactive against the soluble glycoproteins of RAVV, SUDV, RESTVp (pig isolate), RESTVm (primate isolate), EBOV, NiV, GhV, or CedV (Table 1). Serum samples from 1 flat-faced fruit bat (*A. planirostris trinitatis)* and 1 greater sac-winged bat (*S. bilineata*) were reactive against RAVV-soluble glycoprotein (Table 1). The highest MFI value relative to negative control was from an *A. lituratus* bat (bat no. 41) against SUDV-soluble glycoprotein (Table 1). Serological reactivity was observed in sample 41 between SUDV, RESTVp, RESTVm, NiV, and GhV and in sample 64 between SUDV and EBOV (Table 1).

Serum samples were also screened by enzyme-linked immunosorbent assay (ELISA) for the presence of antibodies reactive to Nipah F and G glycoproteins. The MFI cutoff value was set as 3 times the standard deviation of the average MFI of naive bat serum from a captive Egyptian fruit bat. The proportions of bat serum samples reactive against Nipah G and F at 1:100 dilution were 29.76% (25 of 84) and 19.05% (16 of 84), respectively (Table 1). Only 2 samples were reactive against Nipah G and F at dilutions of 1:250 or greater. Twelve samples were reactive against Nipah G, but not Nipah F, and 3 were reactive against Nipah F but not Nipah G. All samples that showed reactivity with MIA were reactive to Nipah G at ELISA. However, only 1 sample (bat 41) was reactive to both Nipah G and F at ELISA and Nipah G at MIA.

Previously established panviral RT-PCR assays for high-throughput screening of biologically derived samples were used to detect respirovirus, morbillivirus, henipaivirus, and filovirus RNA [19]. The panfilovirus assay was modified by incorporating sequence information for recently identified filoviruses and validated for specificity and sensitivity. Eight representative filoviruses (Supplementary Figure 1) and 3 representative henipaviruses were used to determine the LOD for the assays by means of ddPCR before bat screening. The average LOD for the representative henipaviruses and filoviruses was 3.2 and 1.5 copies/μL, respectively (Supplementary Table 2). The L gene segment of LLOV generated product only at starting concentrations >1000 copies/μL and was considered an outlier for the LOD. Tissue samples from 78 Trinidad bats were screened for respiroviruses, morbilliviruses, henipaviruses, and filoviruses by means of RT-PCR. Tissues screened were lung, liver, kidney, spleen, and brain. No henipavirus or filovirus RNA was detected in this sample set.

DISCUSSION

Worldwide virus discovery and surveillance efforts have led to the identification of a variety novel European, African and Chinese henipaviruses and filoviruses [16, 19, 21, 22, 24, 33, 36, 45]. In addition, they have identified potential henipavirus circulation in Latin America [46]. The zoonotic and cross-species spillover potential of these novel viruses is currently unknown. However, these discoveries highlight the importance of virus discovery and surveillance efforts for novel henipavirus and filovirus species given their potential public health, economic, and ecological impacts. Therefore, expanding surveillance efforts beyond the known geographic distributions of henipaviruses and filoviruses may shed further light on the ecology and evolutionary history of these important viruses.

In the current study, we screened phyllostomid and emballonurid bat serum and tissue samples from Trinidad for henipaviruses and filoviruses. Eight of 84 bat serum samples were positive at Luminex serology and reacted to ≥1 of the henipavirus or filovirus glycoproteins. Twenty-eight samples were positive for Nipah G, F, or both at ELISA. Of note, the 3 bat species (*A. lituratus, A. planirostris trinitatis,* and *C. perspicillata*) positive for a henipavirus-like antibodies at MIA or ELISA are 3 of the 6 species that were positive for henipavirus-like antibodies in a Brazilian study [46]. One bat species sampled in this study, *A. lituratus*, which was found to have antibodies reactive against filovirus-soluble glycoproteins, was among those predicted to be potential hosts of novel filoviruses based on a study by Han et al [40]. Several bats from this species showed reactivity to both filovirus and henipavirus antigens (including an individual with antibodies against both), a phenomenon also observed in pteropodid bats [24, 47, 48].

The serological IgG reactivity observed in our study is likely due to the circulation of viruses that have surface glycoproteins antigenically related to henipavirus and filovirus glycoproteins used in our assays. Similar serological cross-reactivity has been observed in a study of *Rousettus* bats experimentally challenged with filoviruses [49]. We found some discordance between the serological results of the ELISA against Nipah G and the multiplex Luminex assay that includes Nipah G, specifically that more

Only positive reactivity with the specific assay and glycoprotein is displayed.

Abbreviations: BDBV, Bundibugyo virus; EBOV, Ebola virus; ELISA, enzyme-linked immunosorbent assay; F, fusion glycoprotein; G, attachment glycoprotein; GhV, Ghana henipavirus; G/GP, glycoprotein; HeV, Hendra virus; LLOV, Lloviu virus; MARV, Marburg virus; NiV, Nipah virus; RAVV, Ravn virus; RESTVm, primate isolate; RESTVp, pig isolate; SUDV, Sudan virus; TAFV, Taï Forest virus; UWI, University of West Indies.

[a]ELISA results are reported as the highest dilution for which each sample was seropositive. We report the mean fluorescence intensity (MFI) of the multiplex Luminex assay after subtracting the value of 3 standard deviations plus the mean MFI of the naive serum sample for each antigen.

samples were positive against Nipah G with the ELISA than with the Luminex (Table 1). Most of the samples showing some reactivity against Nipah G with ELISA but not the Luminex assay were not seropositive at dilutions above 1:100, with 2 exceptions in which *A. lituratus* bats (bats 30 and 81 [Table 1]) were seropositive by ELISA for both Nipah G and F at dilutions >1:100.

The multiplex nature of the Luminex assay complicates interpretation of the serological results, because we detected

reactivity against the glycoproteins of unrelated viruses, including filovirus, SUDV, and GhV in serum collected from an *A. lituratus* bat (bat 41 [Table 1]). The specific history of viral exposure is inherently unknown in field-collected samples, and polyclonal serum samples are frequently cross-reactive,; therefore, the conclusions that we can draw from these data are limited. Further efforts to characterize the viral diversity circulating in South American bats are needed to refine these serological assays and allow for the development of specific target antigens.

Although we improved on the sensitivity and specificity of a previously established panfilovirus RT-PCR assay [50–53], we detected no henipavirus or filovirus viral RNA. This is not surprising, given our sample sizes and the comparatively low detection rate of virus shedding compared to that of IgG antibodies against these viruses observed in naturally infected bats in field studies and experimentally infected bats in laboratory studies [54–57]. The geographic distributions of several bat species sampled in our study extend as far as Brazil, where bat serum samples were found to be positive for exposure to henipa-like viruses, with ELISA and immunofluorescence assay [46], suggesting the possibility of widespread circulation of henipa-like viruses in Central and South America. Here we provide evidence for the potential circulation of henipa-like and filo-like viruses in Trinidad. No viral RNA was detected in this set of bat samples using RT-PCR. However, 35.7% of the samples were serologically positive. A primary limitation of our study is the low sample size; prior surveillance studies have found antibody-positive and PCR-positive prevalences for filoviruses as low as 1.7% and 1.9% respectively [11, 58]. Taken together, our findings provide evidence of more widespread geographic distribution of henipaviruses and filoviruses than previously appreciated.

Supplementary Data

Supplementary materials are available at The *Journal of Infectious Diseases* online. Consisting of data provided by the authors to benefit the reader, the posted materials are not copyedited and are the sole responsibility of the authors, so questions or comments should be addressed to the corresponding author.

Notes

Acknowledgments. We thank Friederike Feldmann for preparing the stocks of the respective filoviruses used in this study.

Financial support. This research was supported by the Intramural Research Program of the National Institute of Allergy and Infectious Diseases, National Institutes of Health (grant R15AI089419) and the Defense Threat Reduction Agency, Department of Defense (grant HDTRA1-17-10037).

Potential conflicts of interest. All authors: No reported conflicts. All authors have submitted the ICMJE Form for Disclosure of Potential Conflicts of Interest. Conflicts that the editors consider relevant to the content of the manuscript have been disclosed..

Subject: Fwd: [Call for application] 15th HKU-Pasteur Virology Course: Coronaviruses

Dear All,

I would like to draw your attention on our upcoming Virology course and would be most grateful if you could also circulate this information through your contacts.

Best, Roberto

Date: Wed, 3 Apr 2019 03:36:10 +0800
From: HKU-Pasteur Research Pole of the School of Public Health

Subject: Call for applications 15th HKU-Pasteur Virology Course: Coronaviruses

Message from HKU-Pasteur Research Pole of the School of Public Health

[Call for application] 15th HKU-Pasteur Virology Course: Coronaviruses

Applications are open for the **15th HKU-Pasteur Virology Course** on **Coronaviruses** that will be held from July 7 to 13, 2019 in Hong Kong:

Date: July 7 - 13, 2019

Deadline for application: April 15, 2019

Application form / Tips for application

Most **endemic coronaviruses** (CoV) cause mild respiratory and intestinal infections in animals and humans. The identification of two novel and highly pathogenic coronaviruses as the cause of **SARS** and **MERS** outbreaks has illustrated the risks associated with zoonotic infections from this family of viruses. This course will review our current understanding and knowledge gaps, with special emphasis on the origin, evolution, transmissibility, molecular biology, epidemiological and clinical features of the highly pathogenic SARS-CoV and MERS-CoV. **Practical workshops** will challenge participants to design experimental strategies to mitigate the impact of CoV infections.

Course directors:
Roberto BRUZZONE (Hong Kong); Chris MOK (Hong Kong); Malik PEIRIS (Hong Kong); Noel TORDO (Guinea)

Faculty:
Marcel BOKELMANN (Germany); Roberto BRUZZONE (Hong Kong); Emmie DE WIT (USA); Bart HAAGMANS (Netherlands); Yae-Jean KIM (Korea); Raven KOK (Hong Kong); Mart LAMERS (Netherlands); Eve MIGUEL (France); Jean MILLET (France); Chris MOK (Hong Kong); Malik PEIRIS (Hong Kong); Peter ROTTIER (Netherlands); Zhengli SHI (China); Amy SIMS (USA); Noel TORDO (Guinea); Maria VAN KERKHOVE (Switzerland); Patrick WOO (Hong Kong); Nicholas WU (USA); Jincun ZHAO (USA)

Open to postgraduate students, MD, DVM, postdoctoral fellows and young scientists from Hong Kong and overseas.
Registration fees (HKD 1,500) include accommodation (on sharing twin basis for overseas participants) and food (lunch and coffee breaks). Please return the completed form, including 1-2 letters of recommendation, to hku-pasteur@hku.hk.

The course (MMPH6171) is included in the coursework curriculum for research postgraduate studies of the University of Hong Kong.

Subject: Fwd: R24 Discussion

Guys,
This just came through from NIAID.

I suggest that we talk to her first, then we can talk once we have her input. Want to do it on the 7th?

Cheers,
Jon

Subject: R24 Discussion
To: epstein ecohealthalliance.org>

Hi Jon,

It's been awhile since we've spoken but I hope you are doing well. Jean forwarded me your question about hypothesis-driven research in an R24. In general, I think we should probably schedule a brief call to discuss some of the specifics of R24s but also to hear about what you're thinking in terms of a hypothesis-driven approach (or aim). I've listed below some times that work for me/Jean/Mark, please let me know if any of those would work for your team as well.

October 5th: 9-9:30a (eastern)

October 7th: 3-3:30pm

October 14th: 10-11am, 1-2pm, or 2:30-3:30p

October 15th: 11a-noon or 3-4pm

In the interim though, here are some additional thoughts:

The R24 FOA indicates that this mechanism should be used to develop, maintain, provide a resource, but it doesn't explicitly state that hypothesis-driven research is not allowed. Our branch currently has one other funded R24 for the World Reference Collection of Emerging Viruses and Arboviruses (WRCEVA) at UTMB. This R24 does include hypothesis-driven research; they conduct small research projects that leverages having full access to the collection and to samples gathered through pursuit of adding new items to the collection. This research is usually a discreet, small project so as not to take up a lot of the budget and makes use of the resource to answer significant research questions that others haven't addressed yet and that may be difficult to work into other separate applications. I will have to search for other R24s across the institute that may have included animal model development as part of their aims, but none are coming to mind at the moment that would serve as a good example.

Sincerely, Sara

Sara E. Woodson, PhD

Program Officer

Subject: Invitation to act as a signatory on a Statement of Support for Scientists and Health Professionals of China Combatting 2019-nCoV
Attachment(s): "Statement of support 2019nCoV China Final 020920.docx","Signatory list for Statement of support 2019nCoV China 020920.docx"

Dear Fellow Scientists and Colleagues,

Like most of you, I've been following the events around the emergence of 2019-nCoV in China very closely and have been dismayed by the spreading of rumors, misinformation and conspiracy theories on its origins. Some of these are now specifically targeting scientists and health professionals with whom we've all collaborated for many years, and who have been working extremely hard to fight this outbreak and share data with unprecedented speed, openness and transparency. These conspiracy theories threaten to undermine the very global collaborations that we need to deal with a disease that has already spread across continents. They have been condemned by many of you, including today by the WHO DG, Dr. Tedros Adhanom Ghebreyesus.

Drs. Linda Saif, Jim Hughes, Rita Colwell, William Karesh and **Hume Field** have drafted a simple statement of support for scientists, public health and medical professionals of China fighting this outbreak (attached), and we invite you to join us as the first signatories (a full list of invited signatories is also attached). If you agree, we will add your name and affiliation, and make this letter public, with a sign-up webpage for others to show their support. I will also personally present this at my plenary lecture during the International Congress on Infectious Diseases (ICID) conference in Malaysia in just under two weeks, with the goal of sending our message directly to the region under most pressure from this outbreak. We will also circulate a copy of the letter in Mandarin so that our Chinese colleagues are directly communicated with.

I sincerely hope you can join us in this statement. If you agree to add your support, please reply-all to:

a) confirm your support (a simple 'yes' is fine);

b) confirm your full name and affiliation exactly as you would like these to appear on the statement

Thank you for your consideration and support of the scientific and public health community around the world!

Yours sincerely,

Peter

Statement in Support of the Scientists, Public Health, and Medical Professionals of China Combating the Novel Coronavirus Outbreak

We, the undersigned, are public health scientists who have closely followed the emergence of 2019-nCoV, and are deeply concerned about its impact on global health and well-being. We have watched as the scientists, public health and medical professionals of China, in particular, have worked diligently and effectively to rapidly identify the pathogen behind this outbreak, put in place significant measures to reduce its impact, and share their results transparently with the global health community. This effort has been remarkable.

We sign this statement in solidarity with all scientists and health professionals in China who continue to save lives and protect global health during the challenge of this novel coronavirus outbreak. We are all in this together, with our Chinese counterparts in the forefront, against this new viral threat.

The rapid, open and transparent sharing of data on 2019-nCoV is now being threatened by rumors and misinformation around the origins of this outbreak. We stand together to strongly condemn conspiracy theories suggesting that 2019-nCoV does not have a natural origin. Scientists from multiple countries have published and analyzed 2019-nCoV genomes[1], and they overwhelmingly conclude that this virus originated in wildlife[2-9], as have so many other emerging diseases[10,11]. This is further supported by a letter from the Presidents of the US National Academies of Science, Engineering, and Medicine[12], and by the scientific communities they represent. Conspiracy theories do nothing but create fear, rumors, and prejudice that jeopardize our global collaboration in the fight against this virus. We support the call from the Director-General of the World Health Organization to promote scientific evidence and unity over misinformation and conjecture[13]. We want you, the science and health professionals of China, to know that **we stand with you** in your fight against this virus.

We invite others to join us in supporting the scientists, public health, and medical professionals of Wuhan and across China. Stand with our colleagues on the front-line!

Subject: Invitation to the 8th International Symposium on Emerging Viral Diseases
Attachment(s): "Invitation letter Tony Schountz.pdf"

Dear Dr.Schountz:

The 8th International Symposium on Emerging Viral Diseases will be held in October 20-22, 2018, in Wuhan, China. The biennial symposium is organized by Wuhan Institute of Virology, Chinese Academy of Sciences and has become an important event for leading Chinese and international virologists to discuss cutting-edge science on emerging viruses as well as to foster global collaborations.

Prof Zhengli Shi and Dr.Peng Zhou had a nice experience last year in Colorado when attending the symposium on bat-borne infectious diseases, and we know you have made great contributions to bat virus researches. We sincerely hope that you can attend the symposium. Please find enthe formal invitation letter for the meeting.

If you have any question regarding the conference, please contact me.

Thank you!

Best regards

Ben Hu Ph.D

Research Assistant

Secretary of the 8th International Symposium on Emerging Viral Diseases

Wuhan Institute of Virology, Chinese Academy of Sciences
Wuhan 430071, P.R. China

Fort Collins, CO 80523-1692

Dear Dr. Schountz:

The 8th International Symposium on Emerging Viral Diseases will be held in October 20-22, 2018 in Wuhan, China. The symposium is organized by Wuhan Institute of Virology, Chinese Academy of Sciences, and will cover a variety of topics including pathogen biology of emerging viruses, virus-host interaction, antiviral immunity, etc. This biennial symposium has become an important event for leading Chinese and international virologists to discuss cutting-edge science as well as to foster global collaborations.

It is our great pleasure to invite you to present your work at this symposium. Your accommodation in Wuhan will be covered by the conference. As an invited speaker, your registration fee will be waived. Please note that we are regretfully unable to cover your travel expenses due to budget constrain.

Please submit the abstract of your presentation to the meeting secretary Dr. Ben Hu (huben@wh.iov.cn) by July 31st 2018. We look forward to seeing you in Wuhan.

Sincerely Yours,

Xi Zhou, Ph.D

Subject: IUCN guidelines
Attachment(s): "IUCN infographic FINAL 062220.pdf"

Dear colleagues,

Hot off the press! The IUCN Species Survival Commission Bat Specialist Group has released guidelines for researchers, to prevent the human-to-bat transmission of SARS-CoV-2. Our infographic is attached, and full guidelines available through either link below. Additional products are to follow shortly, tailored for other stakeholder groups. Please feel free to distribute as you see fit.

Best regards,
Rebekah

Colorado State University

Preventing human-to-bat transmission of SARS-CoV-2

Exposure Risks

Contact exposure
Bats coming into contact with contaminated hands or equipment

Aerosol exposure
Infectious droplets from handlers holding bats in close proximity

Environmental exposure
Sharing enclosed, poorly-ventilated spaces with bats, where virus may persist in the air or on surfaces

MAP your plan to prevent transmission to bats!

Mitigation Strategies

Minimize

Delay, prioritize, or avoid handling bats when possible, i.e. implement acoustic surveys

Assess

Postpone handling bats if there is a probability that you have been exposed to SARS-CoV-2 or if you have symptoms

Protect

Adopt practices that reduce exposure, i.e. face covering, gloves, disinfection procedures

IUCN SSC Bat Specialist Group

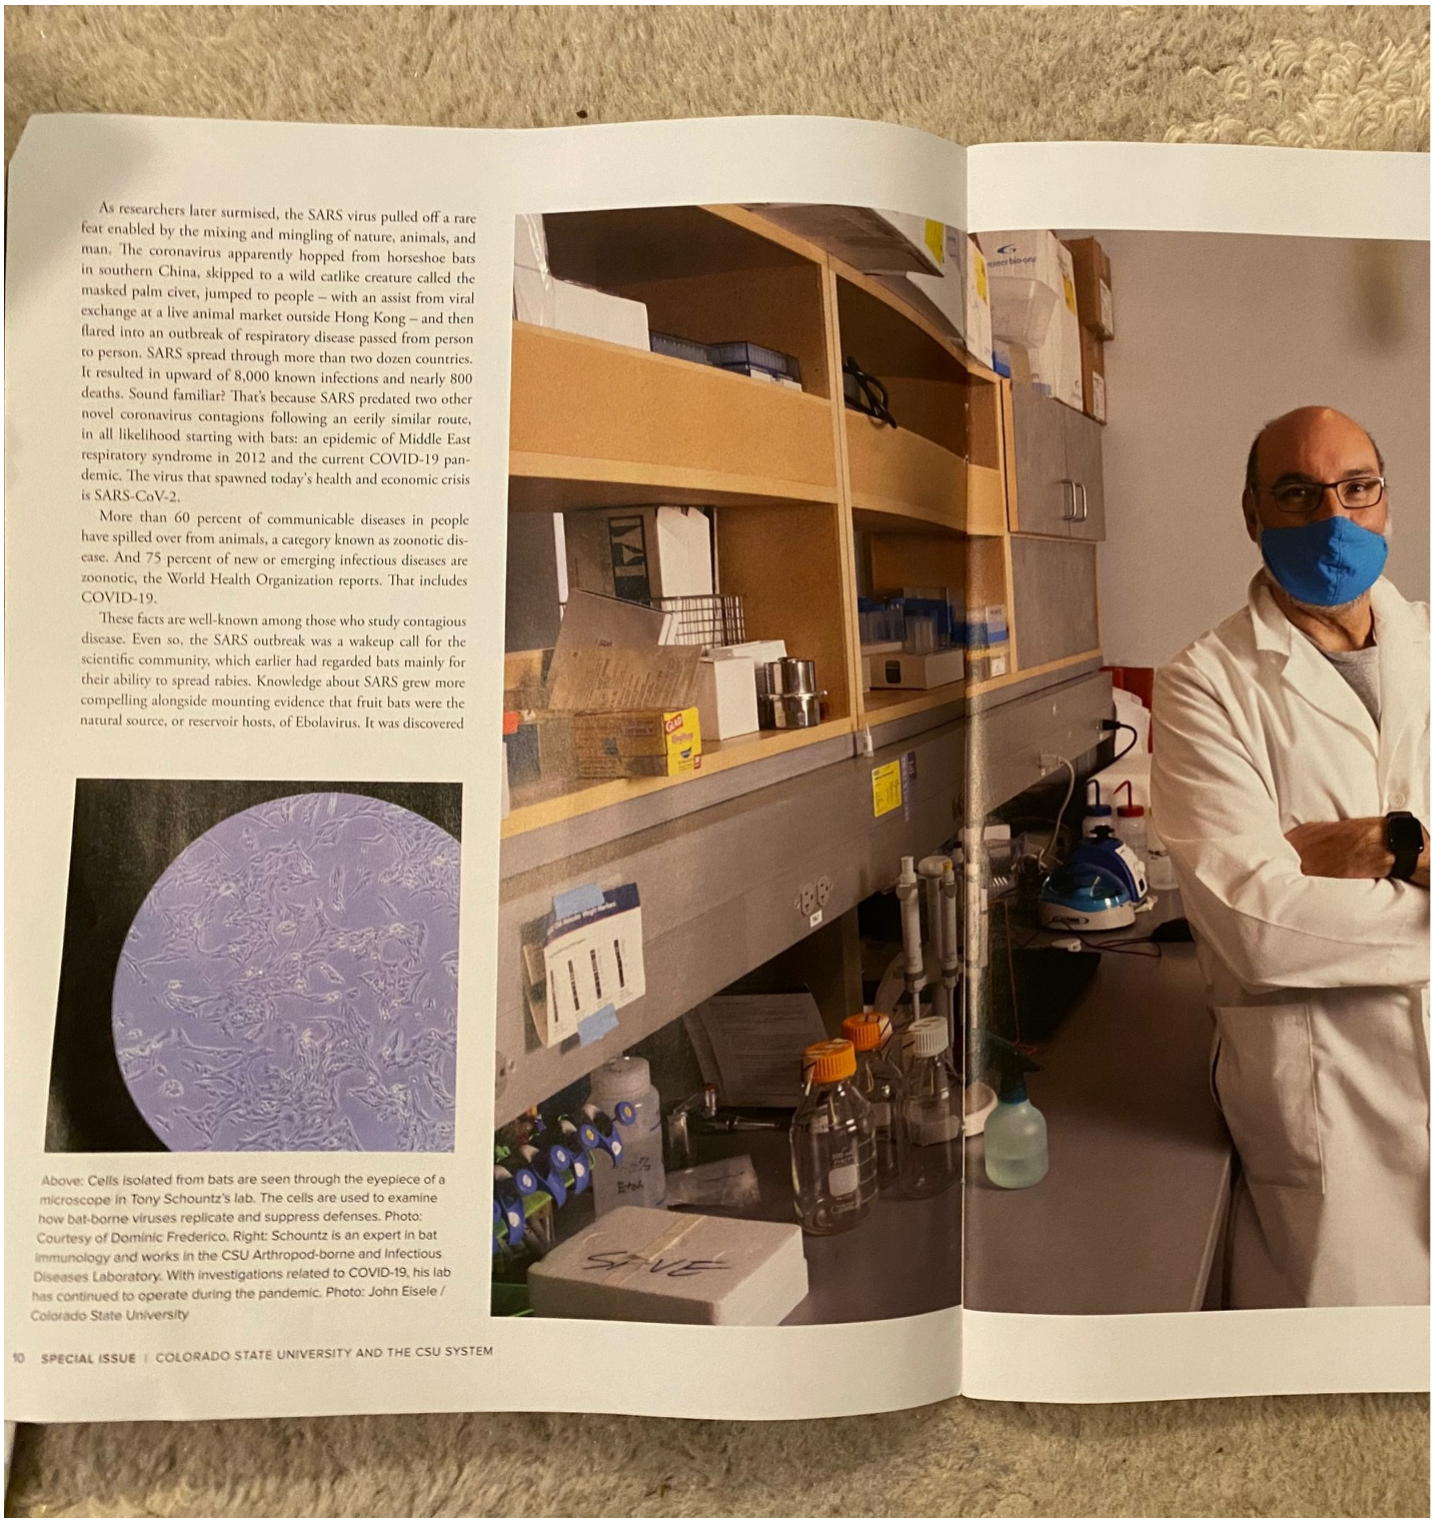
Nice one!

Kevin



As researchers later surmised, the SARS virus pulled off a rare feat enabled by the mixing and mingling of nature, animals, and man. The coronavirus apparently hopped from horseshoe bats in southern China, skipped to a wild catlike creature called the masked palm civet, jumped to people – with an assist from viral exchange at a live animal market outside Hong Kong – and then flared into an outbreak of respiratory disease passed from person to person. SARS spread through more than two dozen countries. It resulted in upward of 8,000 known infections and nearly 800 deaths. Sound familiar? That's because SARS predated two other novel coronavirus contagions following an eerily similar route, in all likelihood starting with bats: an epidemic of Middle East respiratory syndrome in 2012 and the current COVID-19 pandemic. The virus that spawned today's health and economic crisis is SARS-CoV-2.

More than 60 percent of communicable diseases in people have spilled over from animals, a category known as zoonotic disease. And 75 percent of new or emerging infectious diseases are zoonotic, the World Health Organization reports. That includes COVID-19.

These facts are well-known among those who study contagious disease. Even so, the SARS outbreak was a wakeup call for the scientific community, which earlier had regarded bats mainly for their ability to spread rabies. Knowledge about SARS grew more compelling alongside mounting evidence that fruit bats were the natural source, or reservoir hosts, of Ebolavirus. It was discovered

Subject: Meeting agenda

All,

Here is a proposed agenda for tomorrows meeting. Please edit freely.

Introduction
Lon- why meeting was initially organized, then turf to Jon (I won't be long)
Jon- provide background about program discussions with CSU and NIAID and why we are here (Jon really sparked this discussion, and is probably best to lead)
Jean- Discuss NIAID possibilities and expectations and what's needed from CSU (Thought Jean should go sooner to help frame discussion below. I will send her agenda once we get it finalized)
Ebel- Discuss CVID abilities, and possibilities related to emerging disease, prior C06
Tony- Discuss current research and potential needs
Bowen/Angela- Discuss current research and potential needs
Determine next steps

Bat research takes wing

In the field and in the lab, scientists across the globe are working to better understand the biology of the bat

Michael Eisenstein

Bats have a PR problem. In the Western world, at least, they are commonly associated with darkness and filth—and in popular culture, the supernatural forces of evil. But the researchers who actually work with these animals take a different view. "Bats are just such beautiful animals," says Michelle Baker, who studies comparative immunology at the CSIRO Australian Animal Health Laboratory. "They're so gentle."

Unfortunately, their reputation has taken another hit in recent years, with the steady emergence of zoonotic viruses that exploit bats as a Trojan Horse to mount their attack on humanity. These include high-profile threats like Ebola and severe acute respiratory syndrome (SARS) as well as less well-known—but still deadly—viruses like Nipah. "That's a bat virus that is routinely, reliably and predictably spilling over from bats into people," says Jon Epstein, a veterinarian and epidemiologist at the EcoHealth Alliance. "In Bangladesh, it kills about three-quarters of the people that it infects."

The steady emergence of bat-borne viruses has fueled active debate about whether these animals are 'special' in terms of their ability to act as disease hosts. Bats are indeed distinctive in many ways. In addition to being the only mammals capable of powered flight, they are astonishingly diverse and widespread. With over 1,200 species worldwide, bats represent roughly 20% of all mammalian species, with representatives virtually everywhere humans dwell. Bats are also an indisputably rich reservoir for pathogens[1]. "Even if you compensate for research bias in the literature, bats have a disproportionately high number of zoonotic pathogens associated with them compared with other mammals," says Epstein.

Image: Stijn Dijkstra / EyeEm / Getty

Are bats 'special' in their ability to carry disease? Not necessarily, says Tony Schountz. He prefers the word 'different.'

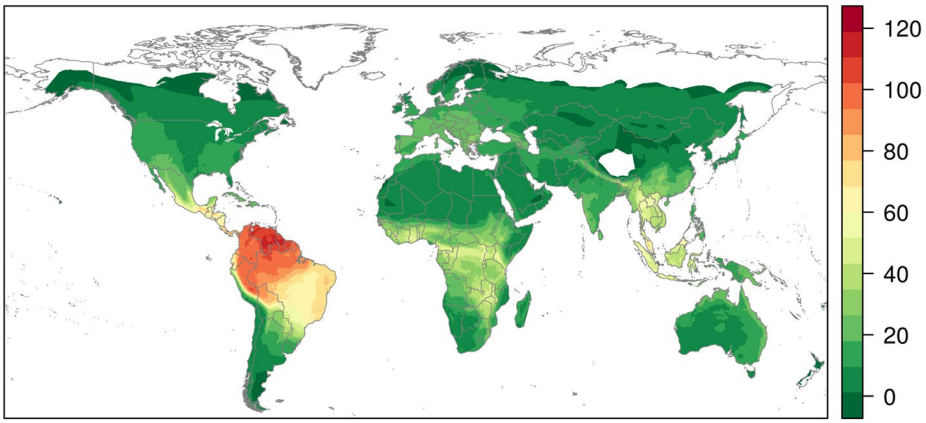
Image: Jackie Strong

However, it remains controversial whether this viral richness arises from unique features of bat immunology and physiology, or merely from bats' capacity to acquire exotic viruses from far and wide and deliver them to human communities. "The word 'special' implies that there's something that makes them better at this, and I don't think that's the case—I prefer the word 'different,'" says Tony Schountz, a microbiologist at Colorado State University. Special or not, researchers are struggling to fill in the blanks about bat biology, and hunting for insights that might clarify why and how bat-borne infections make the leap into humans, and to such deadly effect.

Disease detectives

Historically, bats have mainly been associated with rabies, although they are only seldom responsible for human infection in North America. Bats came back on the radar in the 1990s, with the discovery of the Hendra virus in Australia. "A new virus was isolated from dead horses, and a horse trainer died from the same virus during an outbreak in 1994," says Linfa Wang, director of the Emerging Infectious Diseases Programme at Duke-NUS Medical School. "It took us about a year and a half before we realized that the natural reservoir was bats." In the decade that followed, researchers tied numerous other viral threats to bats, including Nipah, SARS, and Ebola.

It can be difficult to identify the 'spillover' events where these viruses spread to humans. Each outbreak requires careful detective work to identify opportunities for bat-human interaction and obtain molecular confirmation of a shared viral strain between the two species. Most viruses are spread not by bites but through other consequences of close contact that must be pieced together through observation and field work. In Bangladesh, for example, Nipah exposure occurs through the date palm sap that villagers harvest. "Bats visit the pots overnight and lick the sap as it flows down the tree, and sometimes urinate or defecate into the pot," says Epstein, "and a person drinking that sap a few hours later might get infected." In other cases, the route of spillover remains unclear. Baker's



Where to find them: A global map of bat species richness[1]. Copyright 2017 EcoHealth Alliance

lab has studied a wild colony of Australian flying foxes (*Pteropus alecto*) for years, but has yet to learn what causes these bats to 'shed' Hendra virus as a prelude to transmitting infection.

Initial sample collection is often done in a low-tech fashion. "In our studies of paramyxoviruses in sub-Saharan Africa, some of the most important tools we used were plastic sheets," says James Wood, a veterinary epidemiologist at the University of Cambridge. By spreading these under bat roosts, his team could harvest urine and guano for viral profiling. However, evidence of pathogens can often only be detected in blood and saliva—and some bat species live in inaccessible locales or in small numbers rather than large colonies, making it tricky to obtain such samples. Amy Gilbert, a disease ecologist with the US Department of Agriculture, recalls the difficulties she encountered studying Lagos bat virus in African straw-colored fruit bats (*Eidolon helvum*). "They're tree-roosting and migrate really long distances, and the second you get close to the trees they all take off," she says.

Long-term monitoring can reveal patterns of infection and viral transmission over time, but becomes extremely complex for colonies numbering thousands or millions. Epstein's team used RFID tags to 'chip' batches of 100 bats from a large population of Indian flying foxes (*P. giganteus*) in Bangladesh, and only managed 60 recaptures during a six-year-long study[2]. "But that provided tremendous information," he says. "We saw bats that were initially negative for Nipah virus antibodies and were positive at recapture, so we knew they got infected at some point in between."

Safety is also a pressing concern. Most emerging viruses would normally be studied in a tightly-controlled biosafety level (BSL) 4 laboratory, and Epstein notes that field researchers are generally kitted out with full-body protective gear and a respirator, even in the stifling heat of the jungle. Baker likewise notes that personal safety must always be at the front of researchers' minds. "You've just got to be very careful and handle everything as if it's infectious," she says. "'Never get bitten by a bat' is the unspoken rule." Bringing bats 'in-house' to laboratory-based colonies can offer a safer and more controlled research environment than working in the wild, although such efforts are also fraught with challenges (Box 1).

The best defense

Wang recalls stepping into a void when he first began his bat research. "In 1996, if you keyed the words 'bats' and 'immunity' into PubMed, you'd be lucky to get maybe a dozen papers," he says. Fortunately, the ensuing two decades of research have yielded valuable insights.

With some exceptions—most notably, rabies—it seems that the viruses that sicken humans generally do not harm bats. "In all of the experimental viral infections that we've done, our flying foxes just don't

Box 1 | A captive audience

In contrast to the countless rodent vivariums around the world, there are only a handful of such facilities for bats, including colonies at the US Centers for Disease Control and Prevention and the Colorado State University. "We have Jamaican fruit bats in our colony, and so far we've tested six different viruses in our bats," says Schountz, who helped establish the Colorado facility.

Such colonies make long-term studies of viral infection and transmission safer and simpler than working in the field, and eliminate the risk of other infections that could confound the study of a particular pathogen. However, they are also costly and complicated to establish. "In many places, bats are protected and getting permission to catch them is not easy," says Wang, who manages a colony of cave nectar bats (*Eonycteris spelaea*) in Singapore. "Then a young bat takes three years to become sexually mature, and the most active females only have one pregnancy per year with one or two babies per pregnancy." Schountz has had less of a struggle with his colony; Jamaican fruit bats breed every four and a half months, although they still typically only produce one offspring per pregnancy.

Most colonies host fruit-eating bats, which are easy to please from a dietary perspective. Insectivorous bats make far more demanding guests; habituated to hunting flying prey, these bats are reluctant to feed from a dish, and researchers must hand-feed these animals or even put on 'puppet shows'. "We had our BSL4 technicians in full-body spacesuits using forceps with these little worms at the tip, waving them in front of the bats to mimic flying," says Wang.

Far-roaming species may have a hard time coping with captivity, requiring difficult compromises. Wood and his collaborators in Ghana have established a relatively massive *Eidolon helvum* colony. "It's large enough to allow them to fly, and enriched enough that they can roost in relatively normal ways," he says. This requires considerable infrastructure, however, and may not be feasible at many sites. Intermediate-sized pens can be the worst of both worlds. "Some bats will have the wrong perception and think they can fly, and then they'll bump into the cage and get injured," says Wang. His team uses smaller cages to avoid this problem, but this means that the bats are less active than their wild brethren, confounding research into their metabolism and physiology.

Accordingly, every new colony poses a unique challenge, where experience from one species may offer limited insights for another. "We've learned some things from zoos and wildlife parks that do this for a profession," says Wood. "It's something we've put a lot of background work into, and not something I'd undertake lightly."

Bat wrangling: Jon Epstein, pictured in heavy gloves and respirator despite the tropical climate, handles a collared bat in Bangladesh. Image: EcoHealth Alliance 2018

get sick—they don't get a fever, there's just no response at all," says Baker. Epstein has also observed strong indications that many viruses are swiftly defeated by the bat immune system. "They tend to be acute, short-term infections," he says. "For example, we only find about 1–3% of bats in a colony infected with Nipah virus at any given time."

Investigations of bat immunity have uncovered several possible explanations for this apparent tolerance. Baker has found that her bats maintain relatively high levels of interferons, signaling molecules that rouse the initial immune defense against infection and are normally only generated after host immune cells detect a virus. "We think this is giving them a bit of a head start," says Baker. "Then, when they're infected, they can clear the virus much more rapidly." Her bats also seem to mount a different kind of interferon response from humans and rodents, lacking a strong inflammatory component that could otherwise inflict serious tissue damage. Schountz hypothesizes that some viruses survive in bats by churning out interferon-blocking proteins, which could in turn accelerate the evolution of deadlier viruses that can essentially overwhelm the human immune system before it can react. "Human cells may have little chance to combat the virus, which then gets free rein," says Schountz. "That leads to virus replication, and subsequent pathology and cell death."

Wang believes bats may have evolved improved resistance to disease as a consequence of adaptation to the metabolic demands of flight. "During flight, bats' body temperature can go to 38–42 °C, depending on the species, and their heart rate can go up to 1,000 beats per minute," says Wang, who notes that such sustained activity would inflict punishing stress on most organisms, rendering them more vulnerable to disease. "Bats need to have a much more efficient and more finely-tuned defense system," he says.

Starting from scratch

Nevertheless, progress remains slow in untangling the workings of bat immunology due to the limitations of the laboratory toolbox. On one hand, the falling costs and soaring speed and accuracy of DNA sequencing technologies have yielded a steadily growing collection of genome sequences for different bat species. Emma Teeling at University College Dublin is spearheading the ambitious 'Bat 1K Project', which aims to collect genomic data from every bat species on Earth.

However, bat researchers lack many standard reagents that rodent labs take for granted. Cell lines are a powerful resource for gleaning biological insights without the complexity of live animal models, but only a handful are available from bats, and none of these represent the immune cells that respond to viral infection. This has left researchers scrambling for alternatives, such as harvesting and cultivating fresh immune cells from animals for each experiment.

Many experiments rely on antibodies that bind specific proteins, which can be used for applications ranging from imaging to the selective isolation of different cell types. With few bat antibodies commercially available, labs must derive their own. This is time- and labor-intensive, and the result may not be useful across species. "If you were to suggest a researcher should use an antibody developed for a cow in a horse, they'd laugh at you," says Wood. "That's the situation here—these species are very different, and just because we call them all bats doesn't make them close genetically or immunologically."

This highlights another critical challenge. Wang notes that bats diverged evolutionarily from land mammals roughly 100 million years ago, with a second split 30–35 million years later that produced two radically different sub-orders. "The differences between the two can be as big as betweenmice and humans," he says. Most research is focused on known reservoirs of disease, but Baker hopes that heightened interest in bats and the influx of data from projects like Bat 1K will help the community converge on broadly representative 'common denominators'. "We need to get a few model species so we can start sharing reagents and be more productive in what we're doing," says Baker.

Collision course

The extent to which bats are 'unique' as viral reservoirs remains open for debate, but it is indisputable that research into these animals is extremely important from a public health perspective in terms of both known and emerging diseases. "We are discovering loads of new viral sequences, but we don't know about their potential to infect people," says Epstein. And unfortunately, human activity continues to create opportunities for spillover, with ongoing urbanization and agricultural expansion steadily pushing bats and people into closer proximity. Climate change could also increase the risk. For example,

Is a bat a bat? The Jamaican fruit bat (left), cave nectar bat (center), and Indian flying fox (right) are just three of over 1200 different species that can be as varied genetically as mice are to men. Images: Tony Schountz / Linfa Wang / EcoHealth Alliance 2018

Infectious diseases aren't the only reason to study bats. "Modern medicine can learn a lot from bats," says Linfa Wang, in areas like aging and cancer.

Image: Linfa Wang Lab, DukeNUS Medical School

Schountz is monitoring Jamaican fruit bats (*Artibeus jamaicensis*) infected with Tacaribe virus—a pathogen that can sicken and kill these animals. Tacaribe is closely related to numerous dangerous viruses, and although it does not currently infect humans, it could acquire that potential. "The Florida Keys is as far north as they get right now, but climate change seems to be driving this bat species further north," he says. "I get nervous about that."

But some experts also hope the field will move beyond focusing on bats as couriers of disease to explore other unusual characteristics of these animals. For example, Wang notes their exceptional lifespan relative to what scientists would predict based on their body mass and metabolic rate. "A seven-gram bat can live for up to 43 years—that would be roughly equivalent to a human living 1,000 years," he says. He also notes that bats seem to be less prone to cancer, a possible fringe benefit of their finely-tuned 'innate defense system.' "Modern medicine can learn a lot from bats," says Wang.

More generally, Epstein hopes that fears of disease will not cause the public to lose sight of the positive contributions and ecological significance of bats—or the responsibilities humans have towards them. "They're such important animals in terms of pest control and for pollination and seed dispersal," he says. "People are disrupting their environment, and that's causing wildlife pathogens to jump and spill over… it's squarely in our hands to think about that and adjust the way we do things." ❐

Subject: Pteropus space requirements

Hi Brian,
I wanted to introduce you to Professor Greg Ebel, who's the Director of the Arthropod-Borne and Infectious Disease Lab at Colorado State and who's recently become a partner in our efforts, with Tony Shountz, to establish a Pteropus breeding colony there. We're trying to get an accurate understanding of the physical space required for the proposed colony, which if you recall we had discussed starting with 40 bats (4 male, 36 female) which would then become about 60-70 bats post breeding.

Could you help give us a sense of what physical space you think would be necessary in terms of a holding / flight cage, plus support rooms like food storage and a handling / exam area? We've got an existing building on campus that's abou 2500 sq ft that could be gutted & equipped as needed, but the concern is that it's just not big enough for the planned number of bats.

Thanks for your help in thinking through this.

Cheers,
Jon

Subject: 3rd International Symposium on Infectious Diseases of Bats, 17-19 June 2020, Fort Collins, Colorado, USA

Dear Colleagues,

Registration is now open for the 3rd International Symposium on Infectious Diseases of Bats. With the emergence of yet another pathogenic coronavirus, we are planning to have an extended session to learn from one another about this new virus and I hope some of you can foster collaborative interactions while you are here. The URL for the meeting is:

http://www.batid.org

Please note a few important dates. **Abstract submission closes on April 17, 2020**. The format of the abstract is indicated on the web site and we ask that you follow it for purposes of continuity in the program. In addition, please send MS Word, Apple Pages or Rich Text files so that we can rapidly build the program. Please DO NOT send a PDF because they are much more difficult to integrate into the program. After you submit your abstract, you should receive a confirmation email. If you do not, please let me know and I'll resolve the issue.

Registration will close on May 1, 2020. Registration will be handled by the Colorado State University Conference Services with a direct link on the Bat ID web site. You can select registration only, or registration with dormitory housing on campus near the conference venue (Lory Student Center). Registration included breakfast for the two days, and the dormitory includes breakfast, too. If you prefer to stay in a hotel, the Fort Collins Hilton (on Prospect Avenue) and the Best Western University Inn are walking distance to campus. Links to these hotels are provided on the Registration page.

We also have the pleasure of hosting**This Week in Virology**. Vincent and crew will record an episode from the meeting.

Please let me know if you have questions or comments.

Thanks very much, and we are looking forward to seeing you again in Fort Collins.

Tony

Dear colleagues,

I am pleased to announce the **3rd International Symposium on Infectious Diseases of Bats** that will be held at Colorado State University in Fort Collins, Colorado, 17 June to 19 June, 2020. The previous meetings were quite successful and led to several new collaborations amongst participants. We hope we can continue to foster interactions and additional collaborations between groups. Please forward this email to colleagues and students that may be interested in the symposium.

We are currently finalizing details of the symposium but I wanted to send this email so that you can add the dates to your calendar if you are interested in attending. The American Society for Virology Annual Conference will also be hosted at CSU in 2020 and it ends on Wednesday, June 17 at noon. Thus, the Bat ID Symposium will follow with a reception on the evening of June 17th and two days of talks and posters on the 18th and 19th. As with previous meetings, we will end each day with an open discussion about bats and their infectious agents.

Should you have questions, please do not hesitate to contact me.

We look forward to hosting you next summer.

Tony, just an FYI, this overlaps (at the tail end) with the World One Health Congress https://onehealthplatform.com/wohc/home. May not be a big deal for most, but I think some of us were going to do the other meeting also. I haven't figured out my travel yet, but nonetheless I'll plan to come to CO so long as I can and really looking forward to this!

Tony,

Abstract attached! Sorry for the delay.

Estimating viral richness and viral sharing in bats: integrating previously-published and newly-acquired field data

Kevin J. Olival[1], Noam Ross[1], Evan A. Eskew[1], Anna R. Willoughby[1], Carlos Zambrana-Torrelio[1], Peter Daszak[1], and PREDICT Consortium[2]

[1] EcoHealth Alliance, New York, NY 10001, USA
[2] http://www.vetmed.ucdavis.edu/ohi/predict/publications/Authorship.cfm

Objectives: A handful of studies published over the last 8 years have sought to identify the host, ecological, and evolutionary factors that best explain species-level differences in viral richness in bats. Similarly, a few studies have also aimed to answer the golden question: Do bats carry a significantly larger number of total viruses, or a larger number or proportion of zoonotic viruses than other mammals? Our objective is to address these critical questions using statistical models and large datasets collated from the literature and acquired from the field. **Methods:** We collated data from the past 75 years of published for over 2800 mammal-virus associations, representing 754 mammal species and 586 ICTV-named viral species. We fit a series of generalized additive models to these data to identify and examine the functional form of significant predictor variables for total and zoonotic viral richness. Using our best-fit models we also estimate expected viral richness for each host species under a scenario of 'maximum' research effort. We map these viruses in geographic space. We also use species accumulation curves to estimate viral richness from standardized, field-acquired data from the USAID PREDICT project (http://www.healthmap.org/predict/). Network models and statistics were used to compare patterns of viral sharing among bats between the literature and field-acquired datasets. **Results:** For the all mammal analyses: The best-fit model for total viral richness per wild mammal species explained 49.2% of the total deviance, and included a per-species measure of disease-related research effort, phylogenetically corrected body mass, geographic range, mammal sympatry, and taxonomy (order) After controlling for research effort, the proportion of zoonotic viruses per species is predicted by phylogenetic relatedness to humans, host taxonomy and human population within a species range—which may reflect human–wildlife contact. We demonstrate that bats harbor a significantly higher proportion of zoonotic viruses than all other mammalian orders. For the bat field-acquired data we show significant differences in viral richness estimates across bat genera and viral family, as well as differences in the rates of saturation. Clustering in bat host-virus networks follow some predictable patterns and identify additional bat species to target for viruses of interest. **Conclusions:** These host-specific analyses and estimates of viral richness, including the unobserved or 'missing' viruses, allow us to better identify and target which species and regions should be preferentially targeted to characterize the global bat virome.

Using serology to understand the dynamics of concurrent viral infections in pteropid bats

Jonathan H. Epstein[1], Noam Ross[1], Ariful Islam[1], Dan Crowley[1,2], Gary Crameri[3], Christopher Broder[4], Linfa Wang[5], and Peter Daszak[1].

4. Uniformed Services University, MD USA
5. Duke-NUS, Singapore

Fruit bats of the genus *Pteropus* are reservoirs for henipaviruses throughout their range. *Pteropus medius* is the natural reservoir for Nipah virus in India and Bangladesh, and mechanisms of spillover to humans primarily involves contamination of date palm sap with excreta. Serological dynamics have provided insight into patterns of Nipah virus infection in this host, but other viruses, including Nipah-like viruses have been identified through pathogen discovery techniques. Little is known about infection patterns of other viruses within this species, or their likelihood of infecting other animals or people. We screened sera from a single population of *P. medius* in Bangladesh collected quarterly over six years for IgG antibodies against henipaviruses (NiV, HeV, CEDV), filoviruses (EBOV, MARV), and Menangle virus, using assays containing virus-specific solubilized glycoproteins or F proteins in a Luminex platform. Here we present preliminary observations of comparative temporal patterns for multiple viral agents that suggest co-circulation in this population. We also discuss challenges in interpretation of serology when studying viral infections in wildlife, particularly when multiple antigenically related viruses may be present.

Hi, Tony,

Any respiratory syndrome is suspicious. I suggest you to do a test in your lab, that is what we do here, just to rule out that possibility.

Best wishes,
Peng

Hi Tony,

That has not been raised to my attention and I will ask clinicians. IF there is a link, I will let you know.

主题: Bat conference advisory committee

Dear colleagues,

We're planning to host the third international bat infectious disease symposium June 18-20, 2020 here in Fort Collins. This coincides with the end of the 2020 ASV meeting that will also be in Fort Collins and which ends on June 17. I will submit an R13 proposal (Conference Support) to NIH in April to get a few thousand dollars to help with student travel awards for the conference. I hope you don't mind, but I would like to list each of you as members of the advisory committee. Probably not too much for you to do, but it will be helpful for the submission. Is that OK? If you plan to attend the bat symposium, I will waive your registration fee.

Thanks,

Tony

Of course!

BTW, I was at NIAID today. Still pushing for a bat model. Eun Chung is really supportive. Just need to find a way to get over the hump!
Does the building at CSU still exist?

Thanks Jean,

This is extremely helpful and I think the right approach long-term. Many thanks for the update. We will still focus on bats and highlight the current importance of CoVs and bats, as it is timely and reasonable to do so, but will also point out the larger goals of the group and facilities.

Thanks again,

Greg

Hi everyone,

We have one update for you. Mark met with Emily and Cristina today and the consensus was that you do not have to focus most of your efforts on coronaviruses research, rather incorporate the idea of this facility to be used as a resource for pandemic preparedness and EIDs. I think you were headed in this direction anyway, but feel free to add additional capacity and thoughts for related research on EIDs. Coronavirus research should be included, but doesn't have to overwhelm the proposal, if you know what I mean.

Great call yesterday!
Jean and Mark

Dear Zhengli,

If there is anything I can do to help you with your travels, please let me know. I can prepare a letter of invitation for you if you need it.

Peng, I'm sorry you cannot make it. I was looking forward to visiting with you about bat immunology. We have tried many ways of making bone marrow dendritic cells and macrophages but with little success. We have tried adapting mouse protocols with artibeus bat cytokine orthologs but the do not work as well with the bats as they do with mice. I am beginning to think the developmental pathways of bats and mice are substantially different.

I am sure all of you are overwhelmed with the coronavirus outbreak. I really hope it subsides soon because it has been really terrible for China.

Be safe.

Subject: Re: Bat ID meeting

Right, Edinburgh. Somehow, I had in my mind it was the EEID meeting in Paris.

We will be sorry to miss your group here, it's always brought good science and information to the symposium.

Let me know if things change and we'll get you in.

Thanks,

Tony

Hi Jon

The Hilton on Prospect is only half a mile from the meeting. Theres also the University Inn Best Western on College Ave that is about a quarter of a mile.

See you in a couple of weeks.

Tony

CC: Laing, Eric ; Broder, Chris (USU-DoD) ; Luke Hamel ecohealthalliance.org>
Subject: Re: Bat MERS-CoV sera for S protein luminex-based assay R&D

Hey Kevin, indeed the seroconversion is very minimal so I don't know if they would be of any use. I'll check once I get back, but you can include that line anyway

Already sharing hamster, camel, mice and NHP sera with Eric and Chris for validation and sensitivity,

Would be good to add an alternate target to the assay as well (like N),

Cheers,

Vincent

Hi Kevin,

How much serum (volume) do you need? We have just finished an infection experiment with our Aj bats but we have not done the serology, yet.

Thanks Vincent. I'll add a line about sharing the sera from bats and others with Eric and Chris.

Will let Eric and Chris comment on the N gene target.

Thanks for the quick reply Tony. Good to hear the work is going on.

I'll let Eric answer the volume issue, I know it's 2uL per run, but not sure how much would be needed in total for the validation process.

Also, I think Eric has already reached out to Vincent about MERS+ bat sera in a separate request. My email falls under the same overall scope of work, and so just letting everyone know this isn't duplicative and keeping everyone in the loop here. Just hopeful we can find some additional $ support for this. Appreciate everyone's collaborative spirit!

Cheers,
Kevin

They were from Lon. He would be the person who would ultimately decide requirements, and he knows that space better than anyone.

I'd like to hear what Brian has to say but don't know him so please reach out if you can.

It seems like we need ~4x the space that we have so even if there was a 100% overestimate on the space needs for Pteropus we'd still be 25K ft2 short.

Subject: RE: C06 update documents

Dear Greg,

Mark and I concur that this updated plan looks terrific! Our next step would be to get on a call with ORIP. I will let Malgorzata Klosek (ORIP) know that this is ready for them. See below her contact info. When you are ready, we (CSU, EcoHealth Alliance, ORIP and NIAID) can discuss with her and her team.

No need for additional letters, I think this team (including Jon of course) speaks for itself.
And I was the one who needed the letter from Vincent as I have to send it forward to our OD office, so you don't have to do anything.

Thanks again and will chat soon,
Jean

Dr. Malgorzata Klosek (Gosha is her nickname)

Subject: C06 update documents

Dear Jean and Mark,

As promised, I'm attaching a two page update on the C06.

It highlights (a) the overall rationale for the project, (b) our vision for how it would be used, and (c) a summary of current bat-focused experimental research that it would support.

The overall picture that I would like to convey is that CSU is an ideal environment for locating a bat facility due to our longstanding interest in emerging zoonotic and vector-borne infections and our commitment to developing infrastructure to support research in this area. I very much hope that this comes through. If you think that there are points that are being missed, please let me know and I can edit further.

I'm also attaching a letter of support from Dr. Vincent Munster at RML. If you think it would be helpful in moving this forward, we can also obtain a letter from EcoHealth alliance supporting the project.

Thanks so much for your attention and do let me know how I can further help move this project forward.

Best regards,

Greg

Subject: RE: C06 update documents

Dear Greg,

Mark and I concur that this updated plan looks terrific! Our next step would be to get on a call with ORIP. I will let Malgorzata Klosek (ORIP) know that this is ready for them. See below her contact info. When you are ready, we (CSU, EcoHealth Alliance, ORIP and NIAID) can discuss with her and her team.

No need for additional letters, I think this team (including Jon of course) speaks for itself.
And I was the one who needed the letter from Vincent as I have to send it forward to our OD office, so you don't have to do anything.

Thanks again and will chat soon,
Jean

Dr. Malgorzata Klosek (Gosha is her nickname)
Director, Division of Construction and Instrumentation, ORIP, OD

Subject: C06 update documents

Dear Jean and Mark,

As promised, I'm attaching a two page update on the C06.

It highlights (a) the overall rationale for the project, (b) our vision for how it would be used, and (c) a summary of current bat-focused experimental research that it would support.

The overall picture that I would like to convey is that CSU is an ideal environment for locating a bat facility due to our longstanding interest in emerging zoonotic and vector-borne infections and our commitment to developing infrastructure to support research in this area. I very much hope that this comes through. If you think that there are points that are being missed, please let me know and I can edit further.

I'm also attaching a letter of support from Dr. Vincent Munster at RML. If you think it would be helpful in moving this forward, we can also obtain a letter from EcoHealth alliance supporting the project.

Thanks so much for your attention and do let me know how I can further help move this project forward.

Best regards,

Greg

Dear Colleagues,

As you may have expected, due to the COVID-19 outbreak, the*3rd International Symposium on Infectious Diseases of Bats* has been canceled. We are considering hosting the meeting in the summer of 2021 if the resources are available to do so. If so, I will send another email this fall altering you.

For those of you who have already paid your registration, you will receive a full refund from the Colorado State University Conference Services. I have been told this can take about a month, so if you have not received a refund by April 20, please email me and I will contact Conference Services.

Thank you for your understanding.

Tony

Dear Colleagues,

Registration is now open for the 3rd International Symposium on Infectious Diseases of Bats. With the emergence of yet another pathogenic coronavirus, we are planning to have an extended session to learn from one another about this new virus and I hope some of you can foster collaborative interactions while you are here. The URL for the meeting is:

http://www.batid.org

Please note a few important dates. **Abstract submission closes on April 17, 2020**. The format of the abstract is indicated on the web site and we ask that you follow it for purposes of continuity in the program. In addition, please send MS Word, Apple Pages or Rich Text files so that we can rapidly build the program. Please DO NOT send a PDF because they are much more difficult to integrate into the program. After you submit your abstract, you should receive a confirmation email. If you do not, please let me know and I'll resolve the issue.

Registration will close on May 1, 2020. Registration will be handled by the Colorado State University Conference Services with a direct link on the Bat ID web site. You can select registration only, or registration with dormitory housing on campus near the conference venue (Lory Student Center). Registration included breakfast for the two days, and the dormitory includes breakfast, too. If you prefer to stay in a hotel, the Fort Collins Hilton (on Prospect Avenue) and the Best Western University Inn are walking distance to campus. Links to these hotels are provided on the Registration page.

We also have the pleasure of hosting**This Week in Virology**. Vincent and crew will record an episode from the meeting.

Please let me know if you have questions or comments.

Thanks very much, and we are looking forward to seeing you again in Fort Collins.

Tony

Hi Jean,

Thanks a lot. We've started our attempts to gauge the actual (as opposed to theoretical) interest at CSU in committing funds to renovate the space we have identified as a candidate for the bat facility. We should have a renovation estimate in fairly short order and then can approach our VPR with some harder numbers. He might then (a) say "go for it!!" or (b) gag and tell us to take a hike.

Let's let this process play out before we all get together on the phone again.

> >
> > Right now I'd like to characterize the localization and expression of gonadotropin inhibitory hormone (GnIH) in bats; it's a neuropeptide that inhibits the downstream signals involved in the hypothalamic-pituitary-gonadal

axis in vertebrates, but has yet to be described in any bat species. This fits into my broad interest of how environmental and social cues modulate reproductive physiology at a molecular level. For this basic early work, I'm looking to find people who are willing to donate existing, or collect, some tissue samples for me to work on in the lab (IHC, qPCR, westerns...). I'm looking for brains and gonads from any species of bat (male and female) either isolated and flash frozen, or fixed in formaldehyde of some kind. If any of you have insight into this that'd be awesome!

After this initial step, I'd also like to do my own field studies (shooting for 2018-2019) to wild-catch some bats across seasons within a region where species exhibit hibernation or torpor, and examine how GnIH and GnRH fluctuate seasonally across reproductive life history stages and suppression. This connects to ideas within the context of energy partitioning and tradeoff, within which I think those of you working in disease dynamics and immunology could be cool collaborators if interested. If I am able to terminally collect samples for myself perhaps others can collect data on immune aspects of the individuals across seasons as well. Just some early thoughts.

Looking forward to any feedback, potential field work training I can get, and maybe even ideas about where I can get tissues to start.

I'm working under the supervision of Dr. George Bentley, developing projects that broadly encompass the ways animals translate environmental cues via neuroendocrinology to support (or inhibit) reproductive physiology. I have a few different project ideas surrounding bat reproductive neuroendocrine regulation that I'd be happy to chat about if anyone is interested, but I'm reaching out to this group to also offer my help, and ask for some help.
>
> - **I'm really interested in gaining some bat field experience and training in wild-capture (handling, mist netting, harp traps, etc.)** as this is something I'd like to do as part of my dissertation but have no experience. If you are planning to do field work of any capacity over the upcoming Spring/Summer and

would like a responsible set of eyes and hands to help, please let me know!

- I'm attempting to get some preliminary data this year regarding localization and expression of a neurohormone that inhibits the HPG axis in vertebrates. I'd like to characterize it in bats as a starting point and build funding proposals off of that for future field studies. This is where I need help - I am hoping to get some donated **brain, ovary, and testes** tissues from a few different bat species for me to do some IHC/gene expression work on. **If anyone has bat tissues of this type that they do not need for their own research programs, I'd love to talk further!** Flash frozen is ideal, and RNAlater or PFA fixed is also okay.

Thanks so much!

Subject: Re: E-introduction

Hi Sarah, Thanks! As for gaining field experience within the next year I think I am limited to North America purely to minimize cost of gaining a foundation of skills/training...but for research questions I am able to develop and field studies I may want to propose for funding, a wider (global) range of locations can certainly be relevant and beneficial!

For all that are curious or may be interested, here's a nutshell explanation of what my science interests are:

Right now I'd like to characterize the localization and expression of gonadotropin inhibitory hormone (GnIH) in bats; it's a neuropeptide that inhibits the downstream signals involved in the hypothalamic-pituitary-gonadal axis in vertebrates, but has yet to be described in any bat species. This fits into my broad interest of how environmental and social cues modulate reproductive physiology at a molecular level. For this basic early work, I'm looking to find people who are willing to donate existing, or collect, some tissue samples for me to work on in the lab (IHC, qPCR, westerns...). I'm looking for brains and gonads from any species of bat (male and female) either isolated and flash frozen, or fixed in formaldehyde of some kind. If any of you have insight into this that'd be awesome!

After this initial step, I'd also like to do my own field studies (shooting for 2018-2019) to wild-catch some bats across seasons within a region where species exhibit hibernation or torpor, and examine how GnIH and GnRH fluctuate seasonally across reproductive life history stages and suppression. This connects to ideas within the context of energy partitioning and tradeoff, within which I think those of you working in disease dynamics and immunology could be cool collaborators if interested. If I am able to terminally collect samples for myself perhaps others can collect data on immune aspects of the individuals across seasons as well. Just some early thoughts.

Looking forward to any feedback, potential field work training I can get, and maybe even ideas about where I can get tissues to start.

Hello all!

My name is Mattina and I'm a first year PhD student at UC Berkeley within the Integrative Biology Dept. I'm working under the supervision of Dr. George Bentley, developing projects that broadly encompass the ways animals translate environmental cues via neuroendocrinology to support (or inhibit) reproductive physiology. I have a few different project ideas surrounding bat reproductive neuroendocrine regulation that I'd be happy to chat about if anyone is interested, but I'm reaching out to this group to also offer my help, and ask for some help.

- **I'm really interested in gaining some bat field experience and training in wild-capture (handling, mist netting, harp traps, etc.)** as this is something I'd like to do as part of my dissertation but have no experience. If you are planning to do field work of any capacity over the upcoming Spring/Summer and would like a responsible set of eyes and hands to help, please let me know!

- I'm attempting to get some preliminary data this year regarding localization and expression of a neurohormone that inhibits the HPG axis in vertebrates. I'd like to characterize it in bats as a starting point and build funding proposals off of that for future field studies. This is where I need help - I am hoping to get some donated **brain, ovary, and testes** tissues from a few different bat species for me to do some IHC/gene expression work on. **If anyone has bat tissues of this type that they do not need for their own research programs, I'd love to talk further!** Flash frozen is ideal, and RNAlater or PFA fixed is also okay.

Thanks so much!

Hi Mattina,

As for gaining relevant field experience, I would keep your eyes on the Eco-Log and/or TAMU job boards for volunteer bat handling gigs. The type of experience you're after will vary by species, habitat, region, etc., so think broadly.

As a side note, you will want to start reaching out to permitting agencies early on, especially if you're planning to sacrifice North American hibernating bats. Many folks are sensitive to the steep population declines caused by WNS and thus may be wary of such studies. In that context, it might be easier to gain experience and develop your project in a tropical system where bats are less threatened (but not by much....)

Jon, any chance you could get *Rousettus leschenaultii* bats? The Ace2 receptor of this species has 16 of the 20 critical spike protein binding residues.

Additional information (please read)

Advantages of a free-access link to your article

There are several advantages to providing you with a free-access link to your article instead of a PDF file, including:

- Access to both the HTML and PDF versions of your article (where available).
- You (and your co-authors) will get free access to the final, published, and authoritative version of your article, which is available from our site whether or not you or they are a subscriber to the journal.
- We guarantee that you (and your co-authors) will have continued access to your article without the responsibility of maintaining and updating these files.
- All the linking and other functionality for your article remains in place.
- We can continue to gather accurate usage statistics for the journal to help us ensure that we continue to provide a good service for authors and readers.

Sharing the free-access article link with your co-authors

This email is only sent to the corresponding author of the article. You are free to share the free-access links with your co-authors and they are free to reuse the links according to the terms set out here. When sharing these links with co-authors, please share these terms and conditions at the same time.

Using the free-access article link

To access your article, click on the 'article (free access)' link above. If you reach a sign-in page, go back to this email and check if there are extra letters or numbers on the line below the URL. If so, the URL has broken over two or more lines and does not get picked up in its entirety by your browser when clicking through. In this case, copy and paste each line into the address bar of your web browser, deleting extra characters (such as < or >) or spaces. This should allow the URL to bypass subscriber sign-in.

Distribution of the free-access article link

You may distribute the free-access link to your article in the following ways:

- Single copies of the link may be shared with interested colleagues who wish to use the article for personal research/study purposes.
- The link may be posted to your personal/institutional website. However, the article should only be viewed from the Oxford Academic website and not posted to your own personal/institutional web site or that of other third parties.
- The link may be deposited into an institutional repository provided that it is not made publicly available until after the journal's embargo period, which can be found from the self-archiving policy link on the relevant journal site.

The free-access article link must not be distributed in the following ways:

- The link must not be shared on third-party commercial platforms.
- The link must not be shared via social media.
- The link must not be shared through subject-based repositories.

If you wish to reference your article on social media or through subject-based repositories, you are free to use the abstract

link instead, if available.

Anyone wishing to make any other use of your article (e.g. commercial reuse) should contact journals.permissions@oup.com for permissions information or see the Publication rights policies webpage.

Advance articles and publication in an issue

The links provided in this email are persistent links that will always take you to your article, even if it is first published as an advance article ahead of being assigned to an issue. Once it has been assigned to a paginated issue, your article will acquire a volume, issue, and page reference. To be alerted when these details are available, please sign up for the journal's new issue alert.

Attachment(s): "bat.anus.jpg"

Hi Charlie, That billboard was great. One of my kids asked yesterday what I thought about a link on the coronavirus by Mercola so I read it--I have clipped part of it. The tissue from the "anus of a bat." Give me a break. This author on the fringe and others who are putting this stuff out for the most part know how to tweak the interest of the general public--pangolins for example seems to be an interesting model animal. CW ps Hi Tom Monath--I remember working with you many decades ago--simpler times and enjoyable times. After the vaccination against yellow fever my arm pit swelled up and when I asked you about it, you said, "better see your doctor." "Dr. Monath you are my doctor" I replied. I recovered to be able to fly fish the next day and haven't gotten YF yet!!!

Subject: Good idea

How to Accelerate the Evolution of a Virus

As explained by Kennedy, the way they accelerate evolution is by taking the coronavirus from the anus of the bat and replicate it in animal tissue such as pangolin kidney tissue. Next, the grown viruses are placed on feral monkey kidney cells, followed by mouse brain tissue.

Each time you transfer the virus to another animal tissue, you increase the risk of zoonotic animal virus contamination in addition to mutations.

Sounds like you dodged the yellow fever virus but not the vaccine.

Subject: Re: Good idea

Hi Charlie, That billboard was great. One of my kids asked yesterday what I thought about a link on the coronavirus by Mercola so I read it--I have clipped part of it. The tissue from the "anus of a bat." Give me a break. This author on the fringe and others who are putting this stuff out for the most part know how to tweak the interest of the general public--pangolins for example seems to be an interesting model animal. CW ps Hi Tom Monath--I remember working with you many decades ago--simpler times and enjoyable times. After the vaccination against yellow fever my arm pit swelled up and when I asked you about it, you said, "better see your doctor." "Dr. Monath you are my doctor" I replied. I recovered to be able to fly fish the next day and haven't gotten YF yet!!!

Subject: Re: Invitation to the 8th International Symposium on Emerging Viral Diseases

Hi Ben,

I have my flight booked and will arrive in Wuhan at 10:00 PM on October 19 (All Nippon Airways **NH 937**). Can you tell me the name and address of the hotel? I will need it for my visa and for my university administrators.

Thank you,

Tony

Subject: Meeting agenda

All,

Here is a proposed agenda for tomorrows meeting. Please edit freely.

Introduction
Lon- why meeting was initially organized, then turf to Jon (I won't be long)
Jon- provide background about program discussions with CSU and NIAID and why we are here (Jon really sparked this discussion, and is probably best to lead)
Jean- Discuss NIAID possibilities and expectations and what's needed from CSU (Thought Jean should go sooner to help frame discussion below. I will send her agenda once we get it finalized)
Ebel- Discuss CVID abilities, and possibilities related to emerging disease, prior C06
Tony- Discuss current research and potential needs
Bowen/Angela- Discuss current research and potential needs
Determine next steps

Lon

Lon V. Kendall, DVM, PhD, DACLAM
Director, Laboratory Animal Resources and
Attending Veterinarian, Colorado State University

Subject: Re: Monoclonal antibodies

Awesome - and agree.
I would like to brainstorm together for the letters before we approach anyone. I'll start a google doc and we can live edit it.
Let's think about who the 'dream team' will be for this.
It also occurred to me - what do you think about building in a facility in Bangladesh where we keep a captive breeding colony, that would serve as a feeder if we need more bats along the way? We could develop and fund a closed colony there, like what Cambridge did in Ghana, and we'd know the status of each bat. Brian Pope would be great at helping set this up. And it would allow the colony at CSU to fluctuate a bit in size, and we could pull in new bats as needed. I think it's a nice insurance policy to support the colony in CO as we develop it. This could be something I would manage - but I think we could convince the govt and if we provide all the funding for construction and upkeep, it could really happen.

Thoughts?

> Jon, I think a really important part of the grant will be to make monoclonal antibodies to various proteins (e.g., CD antigens, cytokines) and cytokines as reagents. If you agree, I'd like to approach a colleague of my, Brian Geiss, to see if he is willing to be on the grant. Recombinant protein expression is his "thing" and he would be a great asset for the grant.

Tony,
I wasn't able to work on this tonight - I'm going to have to pick it up tomorrow afternoon.
I got a letter of support from Vincent.

I don't know either. We could try to catch them while pregnant. I also don't know if there's vertical transmission.
This will be challenging, but I'm confident we can get to a point where we can safely ship. Maybe if they go straight into a BL3 facility, CDC will have less concern.

Dear Cristina, Eun-Chung and Pat,
Attached is a news piece from Nature: Lab Animal, out yesterday, about the current state of bat research and the need for new lab animal models and reagents. It features a few folks you all may know ;)

Hope you're doing well.

Cheers,
Jon

All, just adding Lon Kendall to the email string. He has assured me there is space for the horseshoe bats and probably for the pteropid bats, but he would like to be on the conference call for this discussion.

Alan, can you help arrange the call through your office?

Thanks,

Tony

Hi Linda and all,
Is there any way for this team to jump on a 10 minute call this afternoon or tomorrow morning?
I have news from NIAID to share.
Ideally, 6pm ET

Hi all,
Absolutely. With spring break and school closures I expect that my life will be a bit bananas but let's set up a zoom to discuss. I'll make it work!

Alan and Greg, as you know I chatted with Jon Epstein yesterday. He has had discussions with NIH about interest in having a grant submission regarding bats and SARS-CoV-2 and other coronaviruses. I think the four of us ought to have a conference call next week to see if we can make something work.

Alan, we would need to have access to a room or building large enough to house large flying foxes as well as smaller horseshoe bats. I know the barn at ARBL was once available but I suspect it no longer is?

Thanks,

T.

Good, Tony. We do have a real opportunity here. I spoke with Jean again, and I think if we can find a way to make this work, we'll be in a strong position to get substantial research support from NIH. My gut says that longer-term, if we're successful with the startup, we could find ways to bring in money to expand the infrastructure.

Good luck with these conversations. Please let me know if there's anything you need from me that could help.

Cheers,
Jon

We should discuss whether a smaller founder colony might still make sense given the opportunity we have. I think the consideration is whether the colony could produce a sufficient birth cohort each year to allow for meaningful research. For example, if we reduced the planned size from 40 to 20, with 3 males and 17 females, with 15 expected to produce pups each year, we'd have 35 bats in Y1 - still within capacity. And we could plan to use most if not all of F1. Long term, we would just have to manage the colony to keep it within size. We could selectively breed a subgroup of females in alternate years, as well.

An appropriate exam room should be sufficient to not only perform procedures but also hold bats that may be injured. 300-400 sq. ft. should suffice.

Subject: Pteropus space requirements

Hi Brian,

I wanted to introduce you to Professor Greg Ebel, who's the Director of the Arthropod-Borne and Infectious Disease Lab at Colorado State and who's recently become a partner in our efforts, with Tony Shountz, to establish a Pteropus breeding colony there. We're trying to get an accurate understanding of the physical space required for the proposed colony, which if you recall we had discussed starting with 40 bats (4 male, 36 female) which would then become about 60-70 bats post breeding.

Could you help give us a sense of what physical space you think would be necessary in terms of a holding / flight cage, plus support rooms like food storage and a handling / exam area? We've got an existing building on campus that's abou 2500 sq ft that could be gutted & equipped as needed, but the concern is that it's just not big enough for the planned number of bats.

Thanks for your help in thinking through this.

Cheers,

Jon

Subject: R24 Discussion
To: epstein ecohealthalliance.org>

Hi Jon,
It's been awhile since we've spoken but I hope you are doing well. Jean forwarded me your question about hypothesis-driven research in an R24. In general, I think we should probably schedule a brief call to discuss some of the specifics of R24s but also to hear about what you're thinking in terms of a hypothesis-driven approach (or aim). I've listed below some times that work for me/Jean/Mark, please let me know if any of those would work for your team as well.
October 5th: 9-9:30a (eastern)
October 7th: 3-3:30pm
October 14th: 10-11am, 1-2pm, or 2:30-3:30p
October 15th: 11a-noon or 3-4pm

In the interim though, here are some additional thoughts:
The R24 FOA indicates that this mechanism should be used to develop, maintain, provide a resource, but it doesn't explicitly state that hypothesis-driven research is not allowed. Our branch currently has one other funded R24 for the World Reference Collection of Emerging Viruses and Arboviruses (WRCEVA) at UTMB. This R24 does include hypothesis-driven research; they conduct small research projects that leverages having full access to the collection and to samples gathered through pursuit of adding new items to the collection. This research is usually a discreet, small project so as not to take up a lot of the budget and makes use of the resource to answer significant research questions that others haven't addressed yet and that may be difficult to work into other separate applications. I will have to search for other R24s across the institute that may have included animal model development as part of their aims, but none are coming to mind at the moment that would serve as a good example.

Sincerely, Sara

Sara E. Woodson, PhD

Hi Tony, Jon, and Greg;
Here are the example R24's you may want to look up in NIH Reporter:

R24AI059830 PI: Jacques Robert (University of Rochester, animal model containing)
R24AI120942 PI: Scott Weaver (University of Texas Medical Branch, WRCEVA—no model development but may be relevant if thinking about including training; may also be good to link in with them for potential distribution of critical reagents along with BEI Resources)

As Mark mentioned on the phone, NIAID doesn't allow a lot of R24 grants and thus not many are funded, so there aren't many relevant examples to what you would be putting forth in your R24. Please let me know if you have other questions or concerns!
Happy writing 😊
Sincerely, Sara

Our branch currently has one other funded R24 for the World Reference Collection of Emerging Viruses and Arboviruses (WRCEVA) at UTMB. This R24 does include hypothesis-driven research; they conduct small research projects that leverages having full access to the collection and to

samples gathered through pursuit of adding new items to the collection. This research is usually a discreet, small project so as not to take up a lot of the budget and makes use of the resource to answer significant research questions that others haven't addressed yet and that may be difficult to work into other separate applications. I will have to search for other R24s across the institute that may have included animal model development as part of their aims, but none are coming to mind at the moment that would serve as a good example.

Sara,
Thank you - it would be great to talk. Let's plan for Oct 7th at 3 pm EDT. I'm copying my colleagues Tony Schountz and Greg Ebel at CSU, who will join us.
Cheers,
Jon

Subject: Re: R24

Jon and Greg, my week has pretty much filled up, other than tomorrow morning from 8:30 to 11:00 MST. Next week has a number of openings, though.

I had seen this list, too. I think we could get these tissues but export is always tricky.
We should definitely include it in our proposal.

> Jon, attached is the paper with the ACE2 sequences that led us down the deer mouse path for SARS2 susceptibility. I've highlighted the 7 Rhinolophus species on page 2 as well as the table with the 20 critical amino acids. (Deer mice have 17 of these 20.) So, R. pearsonii is the closest, but I suspect there may be other Rhinolophus species that have not had ACE2 sequences determined that may be closer to the 20 found in humans, and which may be more likely to be susceptible. It would be helpful if we could get as many ACE2 sequences as possible but we'd need access to lung RNA from each of them to do the PCR and sequencing. I'm suspect someone at Wuhan or elsewhere in China are already doing this. Identifying which facilitate virus entry (e.g., transfection experiments) would point to the best candidates for susceptibility and which we would want to import for one-off susceptibility experiments.

Re:
R24

I'm
actually
off that
week -
we're
moving
the
family
back
into
NYC
for the
start of
School
(Sept
10th).

Could
we
meet
the
following
week?

Thanks,

Jon

couple of weeks to hash out the R24 approach, namely to determine the goals and to identify people who need to be involved. How does the week of Sept 7 look? We're taking the kids hiking on Labor Day but otherwise my week is mostly open except for the morning of Thursday, September 10.

noon on the 7th (EDT) is open.
I asked Jean about research and for an example R24. She said she'd send one and get back to us regarding the limitations of an R24.
Cheers,
Jon

Attachment(s): "jmv.25817.pdf"

Jon, attached is the paper with the ACE2 sequences that led us down the deer mouse path for SARS2 susceptibility. I've highlighted the 7 Rhinolophus species on page 2 as well as the table with the 20 critical amino acids. (Deer mice have 17 of these 20.) So, R. pearsonii is the closest, but I suspect there may be other Rhinolophus species that have not had ACE2 sequences determined that may be closer to the 20 found in humans, and which may be more likely to be susceptible. It would be helpful if we could get as many ACE2 sequences as possible but we'd need access to lung RNA from each of them to do the PCR and sequencing. I'm suspect someone at Wuhan or elsewhere in China are already doing this. Identifying which facilitate virus entry (e.g., transfection experiments) would point to the best candidates for susceptibility and which we would want to import for one-off susceptibility experiments.

Abstract

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) causes the recent COVID-19 public health crisis. Bat is the widely believed original host of SARS-CoV-2. However, its intermediate host before transmitting to humans is not clear. Some studies proposed pangolin, snake, or turtle as the intermediate hosts. Angiotensin-converting enzyme 2 (ACE2) is the receptor for SARS-CoV-2, which determines the potential host range for SARS-CoV-2. On the basis of structural information of the complex of human ACE2 and SARS-CoV-2 receptor-binding domain (RBD), we analyzed the affinity to S protein of the 20 key residues in ACE2 from mammal, bird, turtle, and snake. Several ACE2 proteins from *Primates*, *Bovidae*, *Cricetidae*, and *Cetacea* maintained the majority of key residues in ACE2 for associating with SARS-CoV-2 RBD. The simulated structures indicated that ACE2 proteins from *Bovidae* and *Cricetidae* were able to associate with SARS-CoV-2 RBD. We found that nearly half of the key residues in turtle, snake, and bird were changed. The simulated structures showed several key contacts with SARS-CoV-2 RBD in turtle and snake ACE2 were abolished. This study demonstrated that neither snake nor turtle was the intermediate hosts for SARS-CoV-2, which further reinforced the concept that the reptiles are resistant against infection of coronavirus. This study suggested that *Bovidae* and *Cricetidae* should be included in the screening of intermediate hosts for SARS-CoV-2.

KEYWORDS

ACE2, *Bovidae*, *Cricetidae*, intermediate host, SARS-CoV-2

1 | INTRODUCTION

Coronavirus disease 2019 (COVID-19), which was first reported in Wuhan, Hubei province, China, has caused over 80 422 human infections and more than 2984 deaths (as of 4 March 2020) in China.[1,2] The confirmed cases outside China are increasing, which raised major global concern. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was identified to be the pathogen of COVID-19. SARS-CoV-2 has joined SARS-CoV and Middle East respiratory syndrome-related coronavirus (MERS-CoV) as another coronavirus that causes severe respiratory disease and human death.[3,4]

The specificity of the interaction between virus and receptor determines its host range for the virus. Spike protein (S) of SARS-CoV-2 has attracted great attention because of its role in receptor binding. Angiotensin-converting enzyme 2 (ACE2) binds to the receptor-binding domain (RBD) of SARS-CoV-2 S protein and functions as a receptor for SARS-CoV-2.[5,6] The origin of SARS-CoV-2 is considered as bat.[6] However, the intermediate host is unknown. Some studies suggest that pangolin is involved in the evolution of SARS-CoV-2.[7,8] Others suggested that snake and turtles are potential intermediate hosts for SARS-CoV-2.[9,10] In this study, we compared the key amino acids (AAs) in ACE2 from different species for the binding ability to RBD. On the basis of

potential interaction between S protein and ACE2, it was speculated that SARS-CoV-2 preserved the ability to infect *Bovidae* and *Cricetidae* but not snake or turtle.

2 | METHODS

2.1 | Sequence analysis of ACE2

A total of 93 ACE2 protein sequences were selected from 85 mammals, 4 birds, 3 turtles, and 1 snake. These ACEs with their corresponding species are listed as follows: hACE2: *Homo sapiens* (BAB40370.1), RhiACE2: *Rhinopithecus roxellana* (XP_010364367.2), MacmACE2: *Macaca mulatta* (NP_001129168.1), MuseACE2: *Mustela erminea* (XP_032187679.1), CamdACE2: *Camelus dromedarius* (XP_031301717.1), PlACE2: *Procyon lotor* (XP_031301717.1), PcACE2: *Paguma larvata* (AAX63775.1), RmACE2: *Rhinolophus macrotis* (ADN93471.1), RfACE2: *Rhinolophus ferrumequinum* (BAH02663.1), RsACE2: *Rhinolophus sinicus* (ADN93472.1), RlACE2: *Rousettus leschenaultii* (BAF50705.1), SsACE2: *Sus scrofa* (NP_001116542.1), MpfACE2: *Mustela putorius furo* (BAE53380.1), RatACE2: *Rattus norvegicus* (Q5EGZ1), MmACE2: *Mus musculus* (Q3URC9), ClfACE2: *Canis lupus familiaris* (J9P7Y2), FcACE2: *Felis catus* (A0A384DV19), MjACE2: *Manis javanica* (XP_017505752.1), RpACE2: *Rhinolophus pearsonii* (ABU54053.1), PvACE2: *Pteropus vampyrus* (XP_011361275.1), PoaACE2: *Pongo abelii* (NP_001124604.1), EcACE2: *Equus caballus* (F6V9L3), BtACE2: *Bos taurus* (Q58DD0), PtACE2: *Pan troglodytes* (A0A2J8KU96), OraACE2: *Ornithorhynchus anatinus* (F7FDA2), OvaACE2: *Ovis aries* (W5PSB6), PanACE2: *Papio Anubis* (A0A096N4X9), LaACE2: *Loxodonta africana* (G3T6Q2), SsdACE2: *Sus scrofa domesticus* (A0A220QT48), EeACE2: *Erinaceus europaeus* (A0A1S3APE5), OcACE2: *Oryctolagus cuniculus* (G1TEF4), NpACE2: *Nyctereutes procyonoides* (B4XEP4), VvACE2: *Vulpes vulpes* (A0A3Q7-RAT9), PhcACE2: *Phodopus campbelli* (C7ECU7), MaACE2: *Mesocricetus auratus* (C7ECV1), CjACE2: *Callithrix jacchus* (F7CNJ6), SusACE2: *Suricata suricatta* (XP_029786256.1), HgACE2: *Heterocephalus glaber* (A0A0N8EUX7), DoACE2: *Dipodomys ordii* (A0A1S3GHT7), ItACE2: *Ictidomys tridecemlineatus* (XP_005316051.3), CpACE2: *Cavia porcellus* (XP_023417808.1), CgACE2: *Cricetulus griseus* (A0A061HZ66), ChACE2: *Capra hircus*(A0A452EVJ5); BibtACE2: *Bos indicus x Bos taurus* (A0A4W2H3A1), BmACE2: *Bos mutus* (L8I4I4), NlACE2: *Nomascus leucogenys* (G1RE79); CsACE2: *Chlorocebus sabaeus* (A0A0D9RQZ0); MfACE2: *Macaca fascicularis* (A0A2K5X283); PpACE2: *Pan paniscus* (A0A2R9BKD8); CaACE2: *Cercocebus atys* (A0A2K5KSD8); MnACE2: *Macaca nemestrina* (A0A2K6D1N8); MalACE2: *Mandrillus leucophaeus* (A0A2K5ZV99); TsACE2: *Tarsius syrichta* (A0A1U7TY97); PrcACE2: *Propithecus coquereli* (A0A2K6GHW5); UmACE2: *Ursus maritimus* (A0A452TT30); OgACE2: *Otolemur garnettii* (H0WMI5); SbbACE2: *Saimiri boliviensis boliviensis* (A0A2K6SBD4); CciACE2: *Cebus capucinus imitator* (A0A2K5PYM0); GggACE2: *Gorilla gorillagorilla* (G3QWX4); AnACE2: *Aotus nancymaae* (A0A2K5DQI6); ChaACE2: *Chlorocebus aethiops* (Q1LZX8); AmACE2: *Ailuropoda melanoleuca* (G1MC42); VuACE2: *Vombatus ursinus* (A0A4X2M679); UaACE2: *Ursus americanus* (A0A452R1Z9); UahACE2: *Ursusarctos horribilis* (A0A3Q7TE16); PmACE2: *Physeter macrocephalus* (A0A2Y9S5T9); LvACE2: *Lipotes vexillifer* (A0A340Y3Y6); BasACE2: *Balaenoptera acutorostrata scammoni* (A0A452CBT6); DlACE2: *Delphinapterus leucas* (A0A2Y9M9H3); TtACE2: *Tursiops truncatus* (A0A2U4AJL3); NaaACE2: *Neophocaena asiaeorientalis asiaeorientalis* (A0A341BCI8); CuACE2: *Callorhinus ursinus* (A0A3Q7N3M7); NsACE2: *Neomonachus schauinslandi* (A0A2Y9GEI9); TmlACE2: *Trichechus manatuslatirostris* (A0A2Y9E393); EllkACE2: *Enhydra lutriskenyoni* (A0A2Y9KLV0); ClACE2: *Chinchilla lanigera* (C7ECU0); MdACE2: *Monodelphis domestica* (F6WXR7); LpACE2: *Lynx pardinus* (A0A485NF12); PaACE2: *Pipistrellus abramus* (C7ECT9); MbACE2: *Myotis brandtii* (S7N573); DrACE2: *Desmodus rotundus* (K9INV8); RhpACE2: *Rhinolophus pusillus* (E2DHI9); RaACE2: *Rhinolophus alcyone* (A0A0N7IQX6); RlACE2(2): *Rhinolophus landeri* (A0A0P0IB69); MylACE2: *Myotis lucifugus* (G1PXH7), GgACE2: *Gallus gallus* (F1NHR4), ApACE2: *Anas platyrhynchos* (R0LHX5), MgACE2: *Meleagris gallopavo* (G1NPB8), CaaACE2: *Cathartes aura* (A0A091MDI4), OhACE2: *Ophiophagus hannah* (V8NIH2), CpbACE2: *Chrysemys picta bellii* (XP_023964517.1), CmACE2: *Chelonia mydas* (XP_007070561.1); and PsACE2: *Pelodiscus sinensis* (XP_006122891.1). On the basis of known 20 key sites in human ACE2 interacting with SARS-CoV-2 RBD,[11] we analyzed whether these sites were conserved on other ACE2 proteins. Phylogenetic and molecular evolutionary analysis of ACE2 protein was conducted using molecular evolutionary genetics analysis version X (MEGA-X).[12] Phylogenetic tree was generated with Jones-Taylor-Thornton evolutionary model using a maximum-likelihood method.

2.2 | Structure simulation of ACE2-RBD complex

On the basis of the structure of hACE2 with SARS-CoV-2 S RBD (PDB: 6LZG), the structure of SARS-CoV-2 S and ACE2 from *Bos taurus*, *Cricetulus griseus*, *Pelodiscus sinensis*, and *Ophiophagus hannah* were simulated by SWISS-MODEL online server[13] and analyzed by Chimera software version 1.14.[14]

3 | RESULTS

3.1 | Sequence alignment of ACE2

According to the recently resolved structure of the complex of human ACE2 and SARS-CoV-2 RBD, there are 20 key AAs in hACE2 for interacting with RBM.[11] We analyzed those AAs of ACE2 protein from a list of mammals, birds, turtles, and snake, as shown in Table 1. Next, a phylogenetic tree for mammalian ACE2 proteins was constructed by MEGA-X software. There were 16 *primates* ACE2, 5 *Bovidae* ACE2, 2 *Cricetidae* ACE2, and 3 *Cetacea* ACE2 (Table 1 and Figure 1A), possessing at least 90% (18/20) critical AAs. Pangolin ACE2 preserved only 70% (14/20) AAs. Nearly half of the key residues in turtles (CpbACE2, CmACE2, and PsACE2) and snake (OhACE2) were changed (Table 1). ACE2 from *Aves*, including *Gallus gallus*, *Anas platyrhynchos*, *Meleagris gallopavo*, and *Cathartes aura*, only matched 10 to 11 AAs (Table 1).

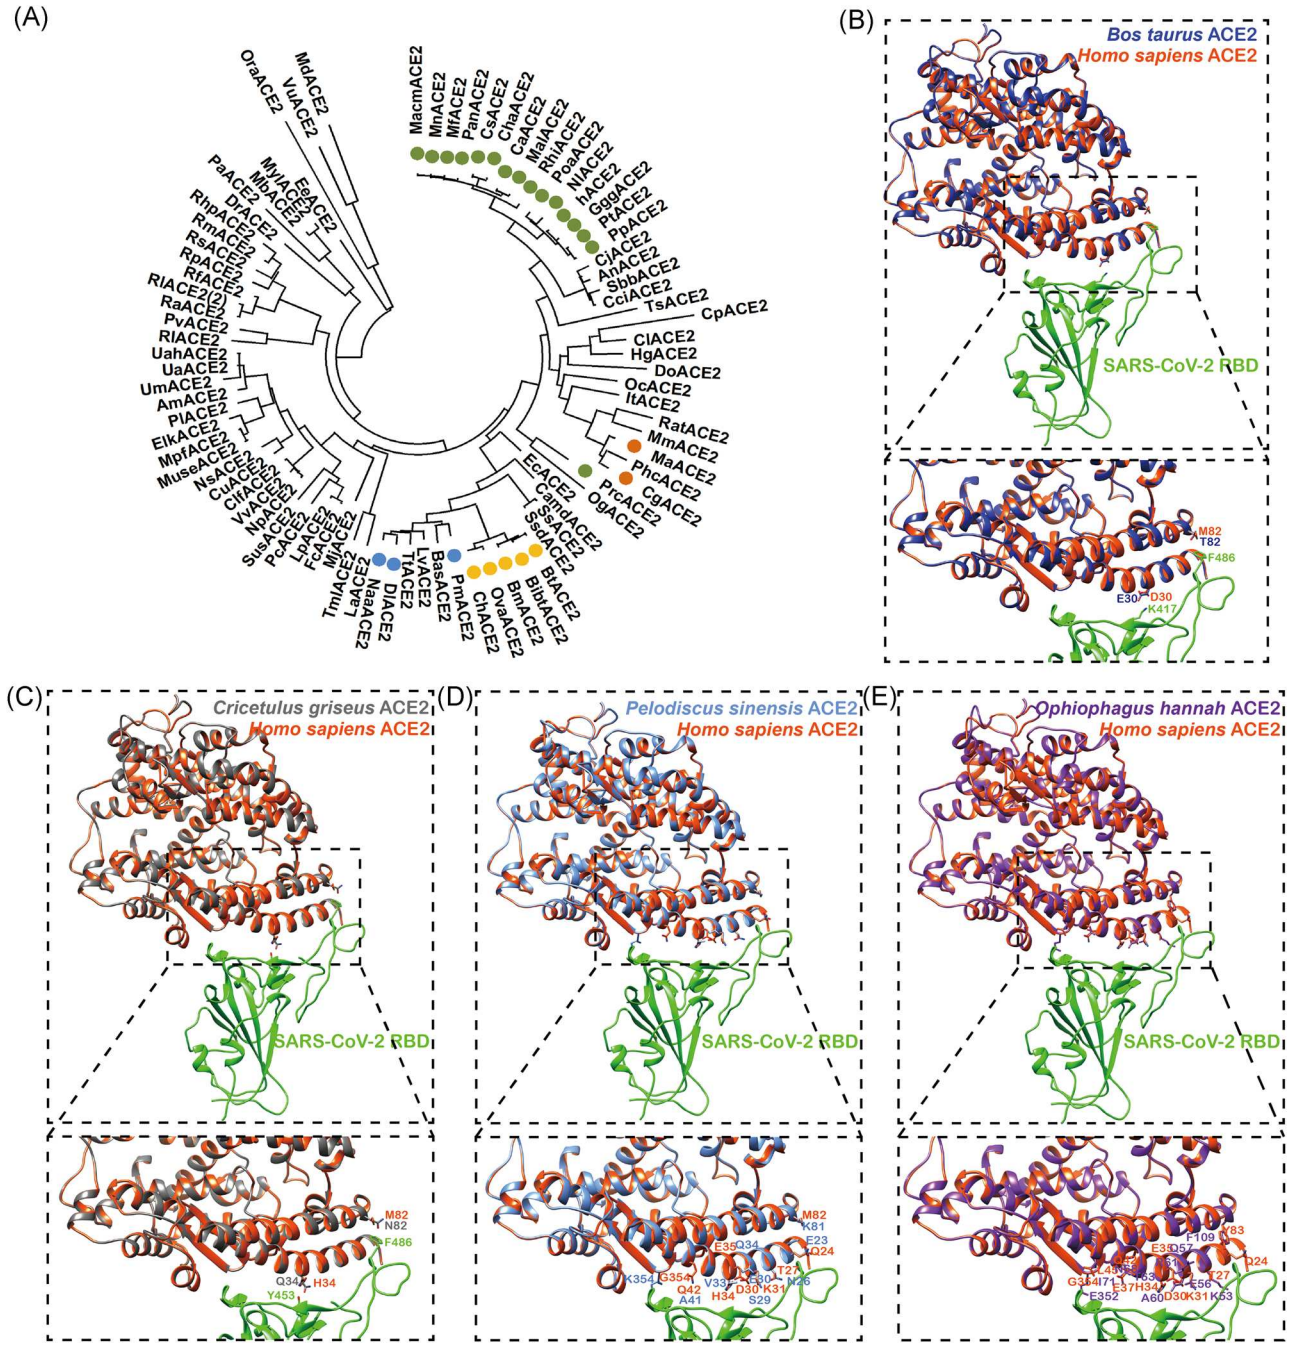

FIGURE 1 Structure simulation of SARS-CoV-2 RBD with ACE2 from different species. A, Phylogenetic tree of mammalian ACE2. ACE2 proteins from a total of 85 mammals were analyzed by MEGA-X and the phylogenetic tree was constructed using a maximum-likelihood method. The green, yellow, orange, and blue represent ACE2 from *Primates*, *Bovidae*, *Cricetidae*, and *Cetacea*, respectively. B, Structural simulation of the protein complex of *Bos taurus* ACE2 and SARS-CoV-2 RBD. *Bos taurus* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in medium blue, orange red, and green, respectively. C, Structural simulation of the protein complex of *Cricetulus griseus* ACE2 and SARS-CoV-2 RBD. *Cricetulus griseus* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in dim gray, orange red, and green, respectively. D, Structural simulation of the protein complex of *Pelodiscus sinensis* ACE2 and SARS-CoV-2 RBD. *Pelodiscus sinensis* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in cornflower blue, orange red, and green, respectively. E, Structural simulation of the protein complex of *Ophiophagus hannah* ACE2 and SARS-CoV-2 RBD. *Ophiophagus hannah* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in purple, orange red, and green, respectively. ACE2, angiotensin-converting enzyme 2; MEGA-X, Molecular Evolutionary Genetics Analysis version X; RBD, receptor-binding domain; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2

3.2 | Structure simulation of the protein complex of SARS-CoV-2 RBD and *Bovidae/Cricetidae*/turtle/snake ACE2

Recently, the structure of SARS-CoV-2 RBD with human ACE2 has been resolved. To investigate whether *Bovidae/Cricetidae* ACE2 maintained the binding affinity with SARS-CoV-2 RBD, we simulated the potential structure of the protein complex. T82 and E30 in *Bos taurus* ACE2 kept the contact to F486 and K417 in SARS-CoV-2 S (Figure 1B). N82 and Q34 in *Cricetulus griseus* ACE2 maintained the contact to F486 and Y453 in SARS-CoV-2 S (Figure 1C). We concluded that *Bovidae/Cricetidae* ACE2 could associate with SARS-CoV-2 S (Figure 1B,C).

To investigate the potential association between SARS-CoV-2 and ACE2 from turtle and snake, we simulated the potential structure of turtle/snake ACE2 with SARS-CoV-2 RBD. The AA correlated to hACE2 Q42 is changed to A (A41) in turtle (Figure 1D). We also noticed that the AA correlated to hACE2 H34 is changed to A (A60) in a snake (Figure 1E). When the contact AA was mutated to smaller AA (A), the contact force for protein-protein interaction will be reduced. Moreover, the corresponding AA of K31 was changed to E (E30) in turtle and Q (Q57) in snake ACE2 (Figure 1D). K31 in hACE2 was critical for SARS-CoV RBD binding and ACE2-K31D mutant abolished its association with SARS-CoV RBD.[15] Taken together, turtle and snake ACE2 are unlikely to bind to S protein of SARS-CoV-2.

4 | DISCUSSION

SARS-CoV, MERS-CoV, and SARS-CoV-2 have caused severe human infectious diseases in the last 2 decades. These three human coronaviruses originated from bats, but the intermediate hosts were different. SARS-CoV came from the *Paguma larvata*,[16] and the intermediate host for MERS-CoV is *Camelus dromedaries*.[17] The new coronavirus SARS-CoV-2 has recently caused a serious pandemic in China and other countries. However, it is not clear which animals are involved in the evolution of SARS-CoV-2 and which animals may be infected by SARS-CoV-2. RBD region in S protein of pangolin coronavirus is similar to that of SARS-CoV-2,[7,8] indicating the involvement of pangolin in the recombination of SARS-CoV-2. By analyzing the codon usage of SARS-CoV-2, people suggested that snake might be a potential host for SARS-CoV-2.[9] Another study indicated that turtle is a potential intermediate host for SARS-CoV-2 based on the key AAs in ACE2 for interacting with SARS-CoV RBD.[10] The late study raised the concerns of SARS-CoV-2 infection in the turtle aquaculture and pet turtle. Most of the coronaviruses hosts are mammals; with a few of exceptions are birds. Considering that all known hosts for coronaviruses are thermostatic animals, it is unlikely that reptiles will be infected with SARS-CoV-2.

There are 20 key AAs in ACE2 critical for binding S protein of SARS-CoV-2.[11] On the basis of these 20 AAs, we analyzed the corresponding AAs in ACE2 from a list of mammal, bird, turtle, and snake. We found that the ACE2 of turtles and snake lost the capability to associate with S protein (Table 1 and Figure 1D,E). These reptiles should be ruled out from the potential host list for SARS-CoV-2. *Aves* ACE2 was unlikely to associate with SARS-CoV-2 RBD because they lost the critical K corresponding to K31 in human ACE2 (Table 1). Pangolin ACE2 was predicted to recognize SARS-CoV-2 RBD less efficiently because it only preserved 14 of 20 critical AAs (Table 1). Interestingly, we found that ACE2 proteins from *Primates*, *Bovidae*, *Cricetidae*, and *Cetacea* were capable to recognize RBD of SARS-CoV-2 by maintaining the majority of key residues in ACE2 for associating with SARS-CoV-2 RBD. Swine ACE2 (CpACE2) with 15 of 20 matched critical AAs was shown to support SARS-CoV-2 entry.[6] *Bovidae/Cricetidae* ACE2 matched more AAs than swine ACE2, thus they should recognize SARS-CoV-2 RBD. It would strengthen our conclusion if we have biochemical evidence for the S-ACE2 interaction analysis for *Bovidae/Cricetidae* ACE2. On the basis of human ACE2 and SARS-CoV-spike complex structure model (PDB ID: 2AJF), we and others recently predicted that hamster ACE2 could associate with SARS-CoV-2 and hamster might be a candidate small animal model for SARS-CoV-2 infection.[18,19] Indeed, golden Syrian hamster (*Mesocricetus auratus*) has been established as a model to study the pathogenesis and transmission of COVID-19.[19] One of *Cetacea*, *Neophocaena asiaeorientalis asiaeorientalis* (Yangtze finless porpoise), lives in the middle and lower reaches of the Yangtze River and its lakes, where Wuhan located nearby.[20] It will be interesting to investigate whether Yangtze finless porpoise could be infected with SARS-CoV-2 or related coronavirus.

In conclusion, we found that *Bovidae/Cricetidae* ACE2 but not turtle/snake ACE2 could recognize SARS-CoV-2 RBD. More attention should be paid to *Bovidae* and *Cricetidae* in hunting the potential intermediate host for SARS-CoV-2.

Subject: R24

Greg and Jon, I think we ought to schedule a conference call in a couple of weeks to hash out the R24 approach, namely to determine the goals and to identify people who need to be involved. How does the week of Sept 7 look? We're taking the kids hiking on Labor Day but otherwise my week is mostly open except for the morning of Thursday, September 10.

Tony

Hi Ben,

My arrival is flight NH 937 (Air Japan), Friday, Oct 19 at 10:00 PM.

My departure is flight NH 938, Tuesday, October 23 at 9:35 AM.

My CV is quite lengthy. Do you want me to send an abbreviated version?

Thank you,

Tony

Hi Dr.Shountz:

There is no problem about the invitation letter with the official seal. I can prepare it today.

Is a scanned copy of this letter acceptable for visa application or the embassy must need an original copy?

Thanks

Ben

Hi Ben,

I'm having trouble getting my visa for my visit. Apparently, I need the letter from you that has some kind of seal stamped on it, and this letter requires my passport number is listed on it. That number is . My legal name is **William A Schountz** and this is the name on my passport so the letter should be addressed with that name. Can you mail the letter directly to me at:

William Schountz

It would be helpful to get the letter by the end of next week because I need my passport back by September 14 for upcoming travel. I cannot get the passport back until I have the visa approved.

Thanks,

Tony

Dear Dr.Schountz:

Here is the scanned copy of the invitation letter with official seal. There are also some other speakers from US who requested this letter in our previous symposiums as well as in this year. They used the scanned copy for visa application.

However, if you confirm with the embassy that the scanned copy is not acceptable, I can send the original paper immediately. Do you need us to pay for the parcel or you can pay yourself upon receiving it?

Thanks

Sincerely

Ben

Dear Dr. Schountz:

The 8th International Symposium on Emerging Viral Diseases (ISEVD) will be held in October 20-22, 2018 in Wuhan, China. The symposium is organized by Wuhan Institute of Virology, Chinese Academy of Sciences, and will cover a variety of topics including pathogen biology of emerging viruses, virus-host interaction, antiviral immunity, etc. This biennial symposium has become an important event for leading Chinese and international virologists to discuss cutting-edge science as well as to foster global collaboration.

It is our great pleasure to invite you to attend this symposium and present your work. As an invited speaker, your accommodation in Wuhan will be covered by the conference and your registration fee will be waived. Please note that we are regretfully unable to cover your travel expenses due to budget constrain.

We look forward to seeing you in Wuhan.

Sincerely Yours,

Xi Zhou, Ph.D
Senior Scientist & Professor
Wuhan Institute of Virology, CAS

Peng Zhou, Ph.D

Dear Dr.Schountz:
I am a researcher at Wuhan Institute of Virology, Chinese Academy of Sciences. My colleagues and I are studying bat viruses and we have submitted four abstracts to the 2nd International Symposium on Infectious Diseases of Bats which is going to be held in Fort Collins in June.
The title for the 4 abstracts are:
1) SARS coronavirus may have originated from frequent recombination events betwwen SARS-like coronaviruses in a single horseshoe bat habitat (oral)
2) Dampening of STING-dependent IFN production: an implication of virus tolerance in bats? (oral) ﾟﾟﾟﾟ noticed from the web that this abstract has already been confirmed as oral presentation)
3) Genomic characterization of diverse BatCoV HKU10 and three novel alphacoronaviruses (poster)
4) Genetically diverse filoviruses in Rousettus and Eonycteris spp. bats, China, 2009 and 2015. (poster)
As it is a unique conference specializing on our research area, we are very eager to attend. However, it usually takes at least two months for us to get the US visa due to the complicated procedure of applying for travel permit to Chinese Academy of Sciences and then one month of administrative processing by US embassy. So in order we can make our visit to Colorado in late June, we have to start the process of travel permit and visa application now.
To apply for a travel permit, we are required to submit an invitation letter from the conference organizer. I know for the bat-borne disease meeting, we will know the results of the acceptance of the abstract by May. But it will be late for us to apply for the travel permit and US visa.
Could you please kindly provides four invitation letters to us indicating we will attend the meeting and give presentations? (oral or posters)
It does not matter whether the abstracts will be finally selected as he invitation letters are only for visa application.
We deeply appreciate your understanding and assistance.
Thank you very much!

Hi Ben,

It looks like heavy thunderstorms for my arrival in Tokyo. Hopefully, they will not delay my connection to Wuhan. If I miss the flight to Wuhan, I will email you so that you can let the driver know. Otherwise, I should see him/her in about 24 hours!

Thanks,

Tony

Yes Dr.Schountz.

The pick-up from the airport to the hotel will be arranged.

Safe journey and see you soon.

Best

Ben

web: ecohealthalliance.org

Pathogens transmitted by bat and arthropod vectors continue to burden the health of humans around the world. Bat-associated pathogens, such as the currently circulating SARS-CoV-2, ebolaviruses, Nipah virus, rabies virus and others are among the most impactful and dreaded infections known. Malaria is perhaps the most deadly infection in the tropics. West Nile, chikungunya and Zika viruses have emerged as major global pathogens. Tick-transmitted infections such as Lyme disease and Powassan virus continue to emerge in temperate regions. Agents vectored by bat and/or arthropod vectors thus constitute some of the most feared, difficult and persistent problems affecting human health.

Therefore, Colorado State University (CSU) established the Arthropod-borne and Infectious Disease Laboratory (AIDL) in 1984 to counter these emerging threats. One of the many unique aspects of AIDL includes housing one of the only captive breeding colonies of bats for use in infectious disease research, and BSL2 and BSL3 insectaries. The pandemic spread of SARS-CoV-2 highlights the national need for this unique resource, and the central role that CSU now occupies in the ability of the US to study and design countermeasures against emerging viral threats of this type.

To support research into emerging diseases, CSU committed $22M in 2019 to construct a new building, the Center for Vector-Borne Infectious Diseases (CVID), to replace aging AIDL infrastructure. CVID construction is ongoing and we anticipate moving in in late 2020.

While CSU's commitment of $22M is laudable, it is insufficient to provide adequate housing for the additional bat colonies needed to address the urgent need for research into the biology and emergence of SARS-CoV-2. Further, additional infrastructure within the CVID is required in order to ensure that research focusing on bat-borne diseases is paired with adequate BSL2 lab, tissue culture and other support space.

This proposal, reviewed highly favorably in 2019 but not selected for funding, represents a unique opportunity to rapidly increase US capacity for housing, breeding and using bats in research. In particular, we propose to:

EcoHealth Alliance develops science-based solutions to prevent pandemics and promote conservation

<C06 Update 2020.docx>

--

Emerging zoonotic ~~Pathogens~~viruses originating in bats ~~transmitted by bat and arthropod~~and vector-borne pathogens ~~vectors~~ continue to significantly threaten ~~burden~~ the health of humans and domestic animals around the world. Bat-associated pathogens, such as coronaviruses, including the currently circulating SARS-CoV-2~~,~~; filoviruses (e.g. Ebola and Marburg viruses), and henipaviruses (e.g. Nipah virus), ~~rabies virus and~~ others are among the most high consequence ~~impactful and dreaded infections~~viruses known. Malaria is perhaps the most deadly infection in the tropics. West Nile, chikungunya and Zika viruses have also emerged as major ~~global~~ pathogens globally. Tick-transmitted infections such as Lyme disease and Powassan virus continue to emerge in temperate regions as climate change expands the range tick vectors. Agents hosted by bats and~~/or arthropod vectors~~vector-borne pathogens thus constitute some of the most ~~feared~~important global health challenges and there is data to suggest that the rate of zoonotic disease emergence will continue to accelerate into the future.~~, difficult and persistent problems affecting human health.~~

To meet this challenge,~~Therefore~~, Colorado State University (CSU) established the Arthropod-borne and Infectious Disease Laboratory (AIDL) in 1984 to counter these emerging threats. One of the many unique aspects of AIDL includes housing one of the only captive breeding colonies of bats for use in infectious disease research, and BSL2 and BSL3 insectaries. One of the major challenges for studying the origins, transmissibility and pathogenesis of emerging bat-borne viruses is the lack of bat animal models. The species diversity of bats is second only to rodents among mammals, however, there are key species that have been associated with important groups of zoonotic viruses such as Ebola and Margburg virus, Nipah virus, and SARS and SARS-CoV2-related coronaviruses, and there is growing evidence that bats are physiologically and immunologically unique in their ability to tolerate viral infection, resist cancer, and have disproportionately long lifespans for their size. All of this makes the dearth of facilities capable of housing bats for basic research and the lack of available bat colonies in the United States for use in biomedical investigations a major impediment to basic infectious disease and translational medicine research. The current ~~pandemic spread o~~COVID-19 pandemic~~f SARS-CoV-2~~ highlights the national need for the~~is~~ ~~unique~~proposed facility as a scientific resource, and the central role that CSU now occupies in the ability of the US to study and design countermeasures against emerging viral threats. ~~of this type~~.

To support research into significant known and unknown emerging diseases, including those listed by the WHO R&D Blueprint as the ten most significant infectious disease threats to global health (half of which are bat-associated or vector borne viruses), CSU committed $22M in 2019 to construct a new building, the Center for Vector-Borne Infectious Diseases (CVID), to replace aging AIDL infrastructure. CVID construction is ongoing and we anticipate moving in in late 2020.

While CSU's commitment of $22M is laudable, it is insufficient to provide adequate housing for the additional bat colonies needed to address the urgent need for research into the biology and emergence of SARS-CoV-2, MERS CoV, Nipah virus, Ebola and yet-to-be discovered viral agents ("Disease X") which are statistically most likely to emerge from bat reservoirs. Further, additional infrastructure within the CVID is required in order to ensure that research focusing on bat-borne diseases is paired with adequate BSL2 and BSL 3 lab, tissue culture and other support space.

Commented [JE1]: There's little overlap here, so I'm trying to make sure they're read as two distinct and important categories of human health threats.

Commented [JE2]: I know it's NIAID, but including a One Health perspective here.

Commented [JE3]: Most human impact is from dog-associated rabies, not bats, so it's probably less relevant to this discussion of emerging viruses.

Commented [S4]: This seems out of place in the context of bats (before) and SARS-CoV-2 (after).

Commented [JE5]: I suppose it's too late to change the name of the facility? Can the bat wing (no pun intended) be given a name to reflect the research focus?

This proposal, which scored well~~reviewed highly favorably~~ in 2019 but was not selected for funding, represents a unique opportunity to rapidly increase US capacity for housing, breeding and using bats in biomedical research. In particular, we propose to:

- Develop a state-of-the art facility to house a breeding colony of *Pteropus* fruit bats known to be natural reservoirs for henipaviruses, filoviruses, and coronaviruses. This will be the first of its kind in the world, and will be a critically important resource for developing and generating reagents (e.g. cell lines, validated serology and PCR assays, etc…) studying basic genomics (groundbreaking work has begun in Singapore and Australia on bat viral tolerance using an Australian Pteropus species, and this will allow the US to actively accelerate this area of research by focusing on a natural reservoir for Nipah virus, filoviruses, and coronaviruses; build on the existing immunology and genomics work, and develop new lines of cancer and aging related research by engaging investigators from various centers at NIH, CSU, and around the world. Experimental work involving high containment pathogens (Nipah virus, Ebola, etc..) will be conducted through a partnership with NIAID Rocky Mountain Labs (see Munster letter of support) in Hamilton, MT.

- Import other key bat species (e.g. *Rhinlophus affinis*) and house native North American bat species for use in coronavirus research, including SARS CoV-2 within CVID.

Current Bat Research at CSU

Colorado State University has a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*), one of the most common and largest fruit bats in the New World. This colony was established in 2005 with funds from the NIAID Emerging Virus Disease Unit contract (AI25489) after it was determined that SARS-CoV was a bat-borne virus. Currently funded bat projects are to study SARS-CoV (CSU VPR funding), MERS-CoV (AI140442), bat influenza A viruses (AI134768), henipaviruses (DARPA G228-19-W7329) and rabies virus (DOE B634747). Our long-term goal for this colony is to make it the "bat version" of the laboratory mouse so that we can conduct experimental infections for other researchers, or provide bats to those who may need them for experiments at their institutions.

We have determined the species is susceptible to several viruses, including Zika virus (30716104), H18N11 bat influenza A virus (31527796), Middle East respiratory coronavirus (MERS-CoV) (26899616), Cedar henipavirus (unpublished), Tacaribe virus (22379103) and Bukakata virus (unpublished), the last two of which cause fatal diseases in the bats. We have also established primary cell lines from the species that are susceptible to MERS-CoV (26899616), Zaire ebolavirus (27354372), and Nipah, Hendra and Cedar henipaviruses (unpublished). We have generated a number of reagents, including monoclonal antibodies and recombinant cytokines, virological and immunological methods, large transcriptome data sets (23166587, 28959737), basic physiological parameters (32164795) and we have demonstrated that it can serve as a surrogate bat model organism for the study of bat-borne viruses. Importantly, a genome assembly to 30x coverage is available (NCBI PVKR01).

SARS-CoV Project. We performed an initial susceptibility study of three Jamaican fruit bats and found that all had low levels of viral RNA in oral swabs within a few days after intranasal

Commented [JE6]: SARS COV-2?

inoculation. By day 14, all three bats had seroconverted by ELISA to recombinant SARS-CoV-2 nucleoprotein and by day 24 the titers had increased at least 4-fold for each bat. Thus we are confident that we have established a surrogate bat model for the study of SARS-CoV-2 in bats. We currently have 27 bats enrolled in a challenge and transmission study and are performing serial euthanasia to determine virus kinetics, tissue tropism, host response and transmission dynamics.

April 1st, 2020

Dear Dr. Auchincloss,

It is with utmost pleasure to be able to provide a letter of support for the CSU bat research center. Past outbreaks of bat-borne zoonotic viruses such as coronaviruses, henipaviruses and filoviruses, have had an enormous impact on human and wildlife health. The unpredictability of the zoonotic introductions of these bat-borne limits the potential for effective intervention strategies. Within my research at the NIAIDs Rocky Mountain Laboratories, I have directly focussed on bat-borne viruses such as Nipah virus, Ebola virus, MERS-CoV and now SARS-CoV-2. In particular we have extensive knowledge of bat infection models of ß-coronaviruses (MERS-CoV and WIV-1, in *Artibeus* and *Rousettus* bats) and Nipah virus (*Rousettus* bats) and are one of the few facilities which are completely set-up to perform bat studies in high and maximum containment (including long-term husbandry and on-site veterinary staff) and complete downstream immunological, genetic and virological analyses. In the absence of suitable breeding facilities at intramural NIAID, the addition of a centre focussed on *in vivo* bat research at CSU deserves the NIAIDs unconditional support.

I am underwriting my enthusiasm to continue to collaborate on the development of a bat resource center including breeding colonies of key bat species, at CSU. Having access to natural hosts for coronaviruses, henipaviruses and filoviruses would significantly advance research in infectious disease undertaken by my group and others at RML, and I am committed to working with Drs. Bowen and Schountz at CSU (long standing research collaboration on MERS-CoV) and Dr. Epstein of EcoHealth Alliance (long standing collaboration on the underlying ecological changes driving spillover events of Nipah virus) to develop and use the resources generated through this C06 proposal. The SARS-CoV-2 pandemic marks an occasion which should put renewed focus on detailed studies of bats as reservoirs of emerging diseases. After SARS-CoV-1, MERS-CoV and Ebola virus in West Africa, we have yet another high impact (both from public health as economic perspective) bat-borne disease which justifies the urgent need for facilities in the US for advanced bat infectious disease studies.

Please feel free to contact me with any remaining questions,

Sincerely,

Vincent Munster
Chief, Virus Ecology Section
Laboratory of Virology
Rocky Mountain Laboratories
NIAID/NIH

Greg and Tony,
I wasn't able to work on this much tonight. I'll pick it up tomorrow afternoon and will have you something by the end of the day.

I did get a letter of support from Vincent - just waiting for a signed copy.

Cheers,
Jon

EcoHealth Alliance develops science-based solutions to prevent pandemics and promote conservation

<C06 Update 2020.docx>

Pathogens transmitted by bat and arthropod vectors continue to burden the health of humans around the world. Bat-associated pathogens, such as the currently circulating SARS-CoV-2, ebolaviruses, Nipah virus, rabies virus and others are among the most impactful and dreaded infections known. Malaria is perhaps the most deadly infection in the tropics. West Nile, chikungunya and Zika viruses have emerged as major global pathogens. Tick-transmitted infections such as Lyme disease and Powassan virus continue to emerge in temperate regions. Agents vectored by bat and/or arthropod vectors thus constitute some of the most feared, difficult and persistent problems affecting human health.

Therefore, Colorado State University (CSU) established the Arthropod-borne and Infectious Disease Laboratory (AIDL) in 1984 to counter these emerging threats. One of the many unique aspects of AIDL includes housing one of the only captive breeding colonies of bats for use in infectious disease research, and BSL2 and BSL3 insectaries. The pandemic spread of SARS-CoV-2 highlights the national need for this unique resource, and the central role that CSU now occupies in the ability of the US to study and design countermeasures against emerging viral threats of this type.

Commented [S1]: This seems out of place in the context of bats (before) and SARS-CoV-2 (after).

To support research into emerging diseases, CSU committed $22M in 2019 to construct a new building, the Center for Vector-Borne Infectious Diseases (CVID), to replace aging AIDL infrastructure. CVID construction is ongoing and we anticipate moving in in late 2020.

While CSU's commitment of $22M is laudable, it is insufficient to provide adequate housing for the additional bat colonies needed to address the urgent need for research into the biology and emergence of SARS-CoV-2. Further, additional infrastructure within the CVID is required in order to ensure that research focusing on bat-borne diseases is paired with adequate BSL2 lab, tissue culture and other support space.

This proposal, reviewed highly favorably in 2019 but not selected for funding, represents a unique opportunity to rapidly increase US capacity for housing, breeding and using bats in research. In particular, we propose to:

Current Bat Research at CSU

Colorado State University has a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*), one of the most common and largest bats in the New World. This colony was established in 2005 with funds from the NIAID Emerging Virus Disease Unit contract (AI25489) after it was determined that SARS-CoV was a bat-borne virus. Currently funded bat projects are to study SARS-CoV (CSU VPR funding), MERS-CoV (AI140442), bat influenza A viruses (AI134768), henipaviruses (DARPA G228-19-W7329) and rabies virus (DOE B634747). Our long-term goal for this colony is to make it the "bat version" of the laboratory mouse so that we can conduct experimental infections for other researchers, or provide bats to those who may need them for experiments at their institutions.

We have determined the species is susceptible to several viruses, including Zika virus (30716104), H18N11 bat influenza A virus (31527796), Middle East respiratory coronavirus (MERS-CoV) (26899616), Cedar henipavirus (unpublished), Tacaribe virus (22379103) and Bukakata virus (unpublished), the last two of which cause fatal diseases in the bats. We have also established primary cell lines from the species that are susceptible to MERS-CoV

(26899616), Zaire ebolavirus (27354372), and Nipah, Hendra and Cedar henipaviruses (unpublished). We have generated a number of reagents, including monoclonal antibodies and recombinant cytokines, virological and immunological methods, large transcriptome data sets (23166587, 28959737), basic physiological parameters (32164795) and we have demonstrated that it can serve as a surrogate bat model organism for the study of bat-borne viruses. Importantly, a genome assembly to 30x coverage is available (NCBI PVKR01).

SARS-CoV Project. We performed an initial susceptibility study of three Jamaican fruit bats and found that all had low levels of viral RNA in oral swabs within a few days after intranasal inoculation. By day 14, all three bats had seroconverted by ELISA to recombinant SARS-CoV-2 nucleoprotein and by day 24 the titers had increased at least 4-fold for each bat. Thus we are confident that we have established a surrogate bat model for the study of SARS-CoV-2 in bats. We currently have 27 bats enrolled in a challenge and transmission study and are performing serial euthanasia to determine virus kinetics, tissue tropism, host response and transmission dynamics.

It was a really great experience for me and I was pleased with the talks, posters and how well your team organized and ran the meeting. I hope I can return to the next meeting in two years as I am sure we will have much more data on bats and influenza virus, MERS-CoV and henipaviruses.
>
> I was so struck by the work at the Wuhan Institute of Virology that I spoke briefly to Peng about how your institute and our Arthropod-borne and Infectious Disease Laboratory (AIDL, http://csu-cvmbs.colostate.edu/academics/mip/aidl/Pages/default.aspx) group have so many similarities. I wonder if you might have an interest in forming a loose association between our groups? I don't know how we could manage this, but one feature I envision would be collaboration on relevant projects (e.g., arboviruses and bat-borne viruses) and training of students. So, if you think there might be interest amongst your group, perhaps we can have further discussions about it.

Hi Dr Schountz,

Your flight will be on tomorrow morning at 9:35?

I will be at th hotel at 6:30. I will meet you at the hotel lobby then and ask a vehicle to send you to the airport.

Please also send me your boarding pass and I will print it for you and give you tomorrow morning.

Best

Ben

Dr Schountz

No you need not pay from your side.

I will pay the vehicle for you using a car-calling app.

Btw, you will share one vehicle with the Japanese speaker, Dr Saijo together, as you will fly with the same flight.

Cheers

Ben

Dear Dr. Schountz,

We just interviewed Anna Fagre for a position here at EcoHealth Alliance as a Research Scientist and Project Manager. Our hiring committee thought she was terrific with the right background and attitude for our team. Anna listed you as a reference. If you would be willing to send some comments about Anna, that would be terrific!

I have attached our position advertisement, so you may know more about the position - though based on her skillset, the specifics would evolve a bit. This position would focus primarily on our emerging infectious disease projects based in Southeast Asia including our recently awarded, NIAID funded EID-SEARCH program:

- https://www.ecohealthalliance.org/program/south-east-asia-research-collaboration-hub

I look forward to your reply and should a phone call be more convenient, we could do that as well.

On behalf of our whole committee, I sincerely appreciate your time.

-Aleksei

JOB ADVERTISMENT

POSITION TITLE: Research Scientist and Project Manager

POSITION SUMMARY

Reporting directly to the President, the Research Scientist will assist senior research scientists on our NIH-funded and projects to examine the dynamics of pathogen transmission within and among wildlife populations, livestock, and humans; as well as the risk of spillover, patterns of infection, phylogenetic relationships of emerging zoonotic diseases. The candidate should be self-motivated and proactive. The Research scientist will need to have a collaborative approach to research, a positive attitude towards solving complex problems, and creativity. This position is a critical part of our science base and the will actively and collaboratively engage in expanding the boundaries of our research as well as help create our 'think-tank' on emerging infectious diseases. Above all, a passion for understanding the process of zoonotic disease emergence is key.

RESPONSIBILITIES

- Collaborate and/or lead in the design and implementation of a multi-country field study of zoonotic disease emergence from bats, rodents, and primates as well as the role of human behavior in disease emergence and analyze the resulting data. Extensive foreign travel, particularly in southeast Asia will be expected.
- Work on modeling and other projects that broadly integrate evolutionary, ecological, and biodiversity data into emerging disease and zoonotic disease models.
- Liaise with EcoHealth Alliance and other scientists to generate hypotheses and to assist with development of models and plan avenues of scientific investigation
- Engage with EcoHealth Alliance scientists and consortium partners on our other projects as well as on federally funded programs on AI, Ebola, Nipah, RVFV, and other emerging diseases.
- Work closely with the President, science staff, and collaborators to design and execute analytical projects to understand the process of zoonotic disease emergence including examination of the roles of host-specific and evolutionary drivers of disease emergence.
- Represent EcoHealth Alliance and work with stakeholders and collaborators at local, national, and international levels.
- Manage Staff, liaise with international partners, and report proactively to funders
- Assist with grant and manuscript writing
- Be responsible for grant management and program coordination
- Use a strong fact basis and collaborative approach to formulate alternative and creative solutions to problems and sensitive issues.

QUALIFICATIONS

- Minimum of Ph.D. in: Biology, Ecology, Evolutionary Biology, Public Health, or related field in the life sciences
- Strong quantitative analytical skills
- Experience with statistical analyses, particularly using R
- Experience with phylogenetic and evolutionary analyses a plus.
- Previous experience in public health or infectious diseases
- Previous experience writing grants and with international grants and program administration of large projects with key components including field and laboratory work and analyses
- 1-to-3 years' experience working on projects funded by US Federal agencies as well as prior non-profit, academic, or equivalent positions
- Demonstrated writing and research skills including Publications in peer-reviewed scientific journals
- Ability to conduct literature reviews, data collation and cleaning, and exploratory data analyses
- Strong writing and verbal communication skills with a keen eye for detail
- Proven ability to work independently
- Self-driven, highly motivated, organized, and willing to perform research and administrative duties
- Strong interpersonal skills; a willingness to place team before self and a strong sense of diplomacy
- Previous experience in Southeast Asia is a plus
- Cultural sensitivity
- Willingness to work some mornings, evenings, weekends as necessary
- Fluency in written and spoken English required

At EcoHealth Alliance, our vision is a workplace with a diverse and talented staff where people want to come, to stay, do their best work, and grow. We recruit, employ, train, compensate and promote our staff without regard to race, ethnicity, color, religion, gender, gender identity or expression, sexual orientation, national origin, disability, age, veteran status, or socioeconomic status. This position is based at EcoHealth Alliance in New York City and will entail extensive domestic and international travel. EcoHealth Alliance offers a competitive salary and a comprehensive benefit package including health, dental, and vision coverage, and a 403(b) pension plan. EcoHealth Alliance is proud and deeply committed to being an equal opportunity employer. For further information about EcoHealth Alliance, please visit our website: www.ecohealthalliance.org.

HOW TO APPLY

Send an email with a *single* attachment in PDF format containing (a) a cover letter, (b) CV, and (c) three references to jobs@ecohealthalliance.org with "**2020 RESEARCH SCIENTIST AND PROJECT MANAGER JOB APPLICATION**" in the subject line. If you would like to be considered for more than one job position, please indicate that in your cover letter and list your order of preference. Emails without the subject line or with multiple attachments will not be reviewed. No formal text is required within the body of your email, since emails will not be evaluated. All inquiries will receive an automatic response confirming receipt. *Only* appropriately qualified candidates will be contacted. Closing date for this position: 15th July 2020.

Thank you for your interest in EcoHealth Alliance!

Subject: Requesting invitation letter for visa application

Dear Dr.Schountz:

I am a researcher at Wuhan Institute of Virology, Chinese Academy of Sciences. My colleagues and I are studying bat viruses and we have submitted four abstracts to the 2nd International Symposium on Infectious Diseases of Bats which is going to be held in Fort Collins in June.

The title for the 4 abstracts are:

1) SARS coronavirus may have originated from frequent recombination events betwwen SARS-like coronaviruses in a single horseshoe bat habitat (oral)

2) Dampening of STING-dependent IFN production: an implication of virus tolerance in bats? (oral) 锛￼I noticed from the web that this abstract has already been confirmed as oral presentation)

3) Genomic characterization of diverse BatCoV HKU10 and three novel alphacoronaviruses (poster)

4) Genetically diverse filoviruses in Rousettus and Eonycteris spp. bats, China, 2009 and 2015. (poster)

As it is a unique conference specializing on our research area, we are very eager to attend. However, it usually takes at least two months for us to get the US visa due to the complicated procedure of applying for travel permit to Chinese Academy of Sciences and then one month of administrative processing by US embassy. So in order we can make our visit to Colorado in late June, we have to start the process of travel permit and visa application now.

To apply for a travel permit, we are required to submit an invitation letter from the conference organizer. I know for the bat-borne disease meeting, we will know the results of the acceptance of the abstract by May. But it will be late for us to apply for the travel permit and US visa.

Could you please kindly provides four invitation letters to us indicating we will attend the meeting and give presentations? (oral or posters)
It does not matter whether the abstracts will be finally selected as he invitation letters are only for visa application.

We deeply appreciate your understanding and assistance.

Thank you very much!

Best regards

Ben Hu Ph.D

Dear Hugh Auchincloss,

It is with utmost pleasure to be able to provide a letter of support for the CSU bat research center. Past outbreaks of bat-borne zoonotic viruses such as coronaviruses, henipaviruses and filoviruses, have had an enormous impact on human and wildlife health. The unpredictability of the zoonotic introductions of these bat-borne limits the potential for effective intervention strategies. Within my research (https://www.niaid.nih.gov/research/vincent-j-munster-phd), I have directly focussed on bat-borne viruses such as Nipah virus, Ebola virus, MERS-CoV and now SARS-CoV-2. In particular we have extensive knowledge of bat infection models of ß-coronaviruses (MERS-CoV and WIV-1, in *Artibeus* and *Rousettus* bats) and Nipah virus (*Rousettus* bats) and are one of the few facilities which are completely set-up to perform bat studies in high and maximum containment (including long-term husbandry and on-site veterinary staff) and complete downstream immunological, genetic and virological analyses.

I am underwriting my enthusiasm to continue to collaborate on the development of a bat resource center including breeding colonies of key bat species, at CSU. Having access to natural hosts for coronaviruses, henipaviruses and filoviruses would significantly advance research in infectious disease undertaken by my group and others at RML, and I am committed to working with Drs. Bowen and Schountz at CSU (long standing research collaboration on MERS-CoV) and Dr. Epstein of EcoHealth Alliance (long standing collaboration on the underlying ecological changes driving spillover events of Nipah virus) to develop and use the resources generated through this C06 proposal. The SARS-CoV-2 pandemic marks an occasion which should put renewed focus on detailed studies of bats as reservoirs of emerging diseases. After SARS-CoV-1, MERS-CoV and Ebola virus in West Africa, we have yet another high impact (both from public health as economic perspective) bat-borne disease which justifies the urgent need for facilities in the US for advanced bat infectious disease studies.

Please feel free to contact me with any remaining questions,

Sincerely,

Vincent Munster

Enjoy **rapid** & **free** publication in Virologica Sinica

Virologica Sinica is an academic journal which aims at presenting the cutting-edge basic and applied research on viruses all over the world. The journal publishes peer-reviewed original research articles and reviews, as well as commentaries and letters to the editor, to encompass the latest developments in all branches of virology, including research on animal, plant and microbe viruses. Virologica Sinica, the official journal of Chinese Society for Microbiology, will serve as a platform for the communication and exchange of academic information and ideas in an international context.
The journal is indexed by: Science Citation Index (SCI), JCR, PubMed/Medline, Scopus, BIOSIS, Google Scholar, and SCImago.

About the cover: In this issue, Xi-Juan Liu et al. reported the first observation of Hes1 oscillatory expression in human NPCs, and found HCMV infection disrupting the Hes1 rhythm and down-regulates its expression. The cover is adopted from a two-photon fluorescence image of Hes1 staining in NPCs (kindly provided by Xi-Juan Liu and Min-Hua Luo), and further processed with pseudo-color (in teal) at cytosol part. Like Hes1 rhythm, water lily also holds its own pattern of flowering rhythm. See page 188-198 for details.

Why Virologica Sinica?

- **Global visibility, available in Springer and covered by PubMed/Medline**
- **Rapid peer review and online publishing (approximately 3 weeks)**
- **Official journal of the Chinese Society for Microbiology**
- **No page or color charges, open-access options**
- **Free language editing**

An update: Epstein-Barr virus and immune evasion via microRNA regulation

Free Full Text (HTML) ***Free*** Full Text (PDF)

Lielian Zuo, Wenxin Yue, Shujuan Du, Shuyu Xin, Jing Zhang, Lingzhi Liu, Guiyuan Li, Jianhong Lu

Epstein-Barr virus (EBV) is an oncogenic virus that ubiquitously establishes life-long persistence in humans. To ensure its survival and maintain its B cell transformation function, EBV has developed powerful strategies to evade host immune responses. Emerging evidence has shown that microRNAs (miRNAs) are powerful regulators of the maintenance of cellular homeostasis. In this review, we summarize current progress on how EBV utilizes miRNAs for immune evasion. EBV encodes miRNAs targeting both viral and host genes involved in the immune response. The miRNAs are found in two gene clusters, and recent studies have demonstrated that lack of these clusters increases the $CD4^+$ and $CD8^+$ T cell response of infected cells. These reports strongly indicate that EBV miRNAs are critical for immune evasion. In addition, EBV is able to dysregulate the expression of a variety of host miRNAs, which influence multiple immune-related molecules and signaling pathways. The transport via exosomes of EBV-regulated miRNAs and viral proteins contributes to the construction and modification of the inflammatory tumor microenvironment. During EBV immune evasion, viral proteins, immune cells, chemokines, pro-inflammatory cytokines, and pro-apoptosis molecules are involved. Our increasing knowledge of the role of miRNAs in immune evasion will improve the understanding of EBV persistence and help to develop new treatments for EBV-associated cancers and other diseases.

Research Article

Human cytomegalovirus infection dysregulates neural progenitor cell fate by disrupting Hes1 rhythm and down-regulating its expression

Free Full Text (HTML) ***Free*** Full Text (PDF)

Xi-Juan Liu, Xuan Jiang, Sheng-Nan Huang, Jin-Yan Sun, Fei Zhao, Wen-Bo Zeng, Min-Hua Luo

Human cytomegalovirus (HCMV) infection is a leading cause of birth defects, primarily affecting the central nervous system and causing its maldevelopment. As the essential downstream effector of Notch signaling pathway, Hes1, and its dynamic expression, plays an essential role on maintaining neural progenitor/stem cells (NPCs) cell fate and fetal brain development. In the present study, we reported the first observation of Hes1 oscillatory expression in human NPCs, with an approximately 1.5 hour periodicity and a Hes1 protein half-life of about 17(17.6±0.2) minutes. HCMV infection disrupts the Hes1 rhythm and down-regulates its expression. Furthermore, we discovered that depleting Hes1 protein disturbed NPCs cell fate by suppressing NPCs proliferation and neurosphere formation, and driving NPCs abnormal differentiation. These results suggested a novel mechanism linking disruption of Hes1 rhythm and down-regulation of Hes1 expression to neurodevelopmental disorders caused by congenital HCMV infection.

Development of a reverse transcription quantitative polymerase chain reaction-based assay for broad coverage detection of African and Asian Zika virus lineages

Free Full Text (HTML) ***Free*** Full Text (PDF)

Yang Yang, Gary Wong, Baoguo Ye, Shihua Li, Shanqin Li, Haixia Zheng, Qiang Wang, Mifang Liang, George F Gao, Lei Liu, Yingxia Liu, Yuhai Bi

The Zika virus (ZIKV) is an arbovirus that has spread rapidly worldwide within recent times. There is accumulating evidence that associates ZIKV infections with Guillain-Barré Syndrome (GBS) and microcephaly in humans. The ZIKV is genetically diverse and can be separated into Asian and African lineages. A rapid, sensitive, and specific assay is needed for the detection of ZIKV across various pandemic regions. So far, the available primers and probes do not cover the genetic diversity and geographic distribution of all ZIKV strains. To this end, we have developed a one-step quantitative reverse transcription polymerase chain reaction (qRT-PCR) assay based on conserved sequences in the ZIKV envelope (*E*) gene. The detection limit of the assay was determined to be five RNA transcript copies and 2.94×10^{-3} 50% tissue culture infectious doses ($TCID_{50}$) of live ZIKV per reaction. The assay was highly specific and able to detect five different ZIKV strains covering the Asian and African lineages without nonspecific amplification, when tested against other flaviviruses. The assay was also successful in testing for ZIKV in clinical samples. Our assay represents an improvement over the current methods available for the detection ZIKV and would be valuable as a diagnostic tool in various pandemic regions.

Research Article

Rabies virus co-localizes with early (Rab5) and late (Rab7) endosomal proteins in neuronal and SH-SY5Y cells

Free Full Text (HTML) ***Free*** Full Text (PDF)

Waqas Ahmad, Yingying Li, Yidi Guo, Xinyu Wang, Ming Duan, Zhenhong Guan, Zengshan Liu, Maolin Zhang

Rabies virus (RABV) is a highly neurotropic virus that follows clathrin-mediated endocytosis and pH-dependent pathway for trafficking and invasion into endothelial cells. Early (Rab5, EEA1) and late (Rab7, LAMP1) endosomal proteins play critical roles in endosomal sorting, maturity and targeting various molecular cargoes, but their precise functions in the early stage of RABV neuronal infection remain elusive. In this study, the relationship between enigmatic entry of RABV with these endosomal proteins into neuronal and SH-SY5Y cells was investigated. Immunofluorescence, $TCID_{50}$ titers, electron microscopy and western blotting were carried out to determine the molecular interaction of the nucleoprotein (N) of RABV with early or late endosomal proteins in these cell lines. The expression of N was also determined by down-regulating Rab5 and Rab7 in both cell lines through RNA interference. The results were indicative that N proficiently colocalized with Rab5/EEA1 and Rab7/LAMP1 in both cell lines at 24 and 48 h post-infection, while N titers significantly decreased in early infection of RABV. Down-regulation of Rab5 and Rab7 did not inhibit N expression, but it prevented productive infection via blocking the normal trafficking of RABV in a low pH environment. Ultrathin sections of cells studied by electron microscope also verified the close association of RABV with Rab5 and Rab7 in neurons. From the data it was concluded that primary entry of RABV strongly correlates with the kinetics of Rab-proteins present on early and late vesicles, which provides helpful clues to explain the early events of RABV in nerve cells.

Research Article

Human endogenous retrovirus W env increases nitric oxide production and enhances the migration ability of microglia by regulating the expression of inducible nitric oxide synthase

Free Full Text (HTML) ***Free*** Full Text (PDF)

Ran Xiao, Shan Li, Qian Cao, Xiuling Wang, Qiujin Yan, Xiaoning Tu, Ying Zhu, Fan Zhu

Human endogenous retrovirus W env (HERV-W env) plays a critical role in many neuropsychological diseases such as schizophrenia and multiple sclerosis (MS). These diseases are accompanied by immunological reactions in the central nervous system (CNS). Microglia are important immunocytes in brain inflammation that can produce a gasotransmitter-nitric oxide (NO). NO not only plays a role in the function of neuronal cells but also participates in the pathogenesis of various neuropsychological diseases. In this study, we reported increased NO production in CHME-5 microglia cells after they were transfected with HERV-W env. Moreover, HERV-W env increased the expression and function of human inducible nitric oxide synthase (hiNOS) and enhanced the promoter activity of hiNOS. Microglial migration was also enhanced. These data revealed that HERV-W env might contribute to increase NO production and microglial migration ability in neuropsychological disorders by regulating the expression of inducible NOS. Results from this study might lead to the identification of novel targets for the treatment of neuropsychological diseases, including neuroinflammatory diseases, stroke, and neurodegenerative diseases.

Detection of diverse viruses in alimentary specimens of bats in Macau

Free Full Text (HTML) ***Free*** Full Text (PDF)

Jie Liang, Xing-Lou Yang, Bei Li, Qi Liu, Qin Zhang, Hui Liu, Hon-Pio Kan, Kai-Chin Wong, Si-Nga Chek, Xiangyang He, Xingwen Peng, Zheng-Li Shi, Yi Wu, Libiao Zhang

Bats carry a variety of viruses, and some of them cause public health problems. Macau, which is famous for its gambling industry, has a complex population structure. The globalization in such an international metropolis has enhanced the chance of disease transmission. Therefore, surveillance of zoonotic viruses is necessary for the early warning of potential emerging infectious diseases. Here, we report the first surveillance of bat viruses in Macau. In this study, we collected 1004 samples involving 10 bat species from 7 sites from April 2015 to May 2016, and examined the presence of viruses using nucleic acid-based methods. Coronaviruses, adenoviruses and paramyxoviruses were detected in these samples, with a high prevalence of coronaviruses. While, none was positive for hepatitis A virus, hepatitis E virus or hantavirus. Co-infections are not common in those bat species, but coronavirus HKU6 and adenovirus can be found commonly occurred in *Myotis ricketti*.

Research Article

Phylogenetic analysis based on mitochondrial DNA sequences of wild rats, and the relationship with Seoul virus infection in Hubei, China

Free Full Text (HTML) ***Free*** Full Text (PDF)

Dong-Ying Liu, Jing Liu, Bing-Yu Liu, Yuan-Yuan Liu, Hai-Rong Xiong, Wei Hou, Zhan-Qiu Yang

Seoul virus (SEOV), which is predominantly carried by *Rattus norvegicus*, is one of the major causes of hemorrhagic fever with renal syndrome (HFRS) in China. Hubei province, located in the central south of China, has experienced some of the most severe epidemics of HFRS. To investigate the mitochondrial DNA (mtDNA)-based phylogenetics of wild rats in Hubei, and the relationship with SEOV infection, 664 wild rats were captured from five trapping sites in Hubei from 2000-2009 and 2014-2015. Using reverse-transcription (RT)-PCR, 41(6.17%) rats were found to be positive for SEOV infection. The SEOV-positive percentage in Yichang was significantly lower than that in other areas. The mtDNA D-loop and cytochrome b (*cyt-b*) genes of 103 rats were sequenced. Among these animals, 37 were SEOV-positive. The reconstruction of the phylogenetic relationship (based on the complete D-loop and *cyt-b* sequences) allowed the rats to be categorized into two lineages, *R.norvegicus* and *Rattus nitidus*, with the former including the majority of the rats. For both the D-loop and *cyt-b* genes, 18 haplotypes were identified. The geographic distributions of the different haplotypes were significantly different. There were no significant differences in the SEOVpositive percentages between different haplotypes. There were three sub-lineages for the D-loop, and two for *cyt-b*. The SEOV-positive percentages for each of the sub-lineages did not significantly differ. This indicates that the SEOV-positive percentage is not related to the mtDNA D-loop or *cyt-b* haplotype or the sub-lineage of rats from Hubei.

Letter

Retromer localizes to autophagosomes during HCV replication

Free Full Text (HTML) ***Free*** Full Text (PDF)

Peiqi Yin, Zhi Hong, Leiliang Zhang, Youyang Ke

In summary, we propose a model for the role of retromer in HCV replication. Upon HCV infection, retromer may provide double-membrane autophagosomal membranes for HCV replication. Our studies suggested a novel link between retromer and autophagy in HCV replication, which may provide new therapeutic targets for antiviral therapy.

Letter

Molecular typing of non-polio enteroviruses isolated from acute flaccid paralysis cases in Iran from 2010 to 2015

Free Full Text (HTML) ***Free*** Full Text (PDF)

Ahmad Nejati, Mohammad Farahmand, Hamideh Tabatabaie, Maryam Yousefi, Yaghoob Mollaei-Kandelous, Shohreh Shahmahmoodi

In summary, our findings showed that for correct identification of NPEVs, cell lines other than RD cells must be used. In addition, neutralization tests did not show high sensitivity for identification of all NPEVs. Finally, establishment of direct molecular tests with high sensitivity and specificity is needed to identify NPEV from patient and environmental samples.

Isolation and phylogenetic study of Rift Valley fever virus from the first imported case to China

Free Full Text (HTML) ***Free*** Full Text (PDF)

Yongxia Shi, Kui Zheng, Xiaobo Li, Liqiang Li, Shufen Li, Jinmin Ma, Jun Dai, Jingkai Ji, Shuai Yuan, Haorong Lu, Jiandong Li, Fangfang Sun, Xun Xu, Jicheng Huang

Here, laboratory detection, virus isolation, whole genome sequencing and phylogenetic analysis were performed to characterize the first imported case of Rift Valley fever virus infection returning from Angola.

Letter

CD95-CD95L interaction mediates the growth control of MHV68 immortalized B cells by cytotoxic T cells

Free Full Text (HTML) ***Free*** Full Text (PDF)

Sihan Dong, Lingbing Tan, Guifang Chen, Xiaozhen Liang

In conclusion, our current data demonstrate that MHV68-immortalized SL-1 cells can be recognized and controlled by specific cytotoxic T cells through CD95/CD95L-mediated apoptosis. This is in agreement with that CD4 T cells control the growth of EBV-infected cells through CD95/CD95L-mediated apoptosis, which suggests that the growth control of gammaherpesvirus-associated lymphoma cells by cytotoxic T cell shares conserved mechanism.

Subject: 3rd International Symposium on Infectious Diseases of Bats, 17-19 June 2020, Fort Collins, Colorado, USA

Dear Colleagues,

Registration is now open for the 3rd International Symposium on Infectious Diseases of Bats. With the emergence of yet another pathogenic coronavirus, we are planning to have an extended session to learn from one another about this new virus and I hope some of you can foster collaborative interactions while you are here. The URL for the meeting is:

http://www.batid.org

Please note a few important dates. **Abstract submission closes on April 17, 2020**. The format of the abstract is indicated on the web site and we ask that you follow it for purposes of continuity in the program. In addition, please send MS Word, Apple Pages or Rich Text files so that we can rapidly build the program. Please DO NOT send a PDF because they are much more difficult to integrate into the program. After you submit your abstract, you should receive a confirmation email. If you do not, please let me know and I'll resolve the issue.

Registration will close on May 1, 2020. Registration will be handled by the Colorado State University Conference Services with a direct link on the Bat ID web site. You can select registration only, or registration with dormitory housing on campus near the conference venue (Lory Student Center). Registration included breakfast for the two days, and the dormitory includes breakfast, too. If you prefer to stay in a hotel, the Fort Collins Hilton (on Prospect Avenue) and the Best Western University Inn are walking distance to campus. Links to these hotels are provided on the Registration page.

We also have the pleasure of hosting **This Week in Virology**. Vincent and crew will record an episode from the meeting.

Please let me know if you have questions or comments.

Thanks very much, and we are looking forward to seeing you again in Fort Collins.

Tony

Subject: Bat conference advisory committee

Dear colleagues,

We're planning to host the third international bat infectious disease symposium June 18-20, 2020 here in Fort Collins. This coincides with the end of the 2020 ASV meeting that will also be in Fort Collins and which ends on June 17. I will submit an R13 proposal (Conference Support) to NIH in April to get a few thousand dollars to help with student travel awards for the conference. I hope you don't mind, but I would like to list each of you as members of the advisory committee. Probably not too much for you to do, but it will be helpful for the submission. Is that OK? If you plan to attend the bat symposium, I will waive your registration fee.

Thanks,

Tony

Subject: Bat ID conference

Dear Zhengli and Peng,

I was wondering if you will be attending the bat meeting after ASV. (I realize some of you may be at the Paris meeting instead.) If so, I'd like to list you as confirmed speakers. I'm awaiting a small grant decision from my university that would be used to waive your registration fee if you are a confirmed speaker. The decision is supposed to be made in the next week or two, so I won't be able to let you know for sure until then. I understand you are quite busy with the new coronavirus and that there may be travel issues, but if it is possible for you to make it, I would be most grateful.

Thank you,

Tony

Subject: Bat ID Symposium logistics
Attachment(s): "Campus map.pdf"

Dear Colleagues,

The symposium is one week away and I want to provide you with some logistical information for your arrival to Fort Collins.

1. Speakers. If you can email your presentation directly to me I will get it on the computer for the presentation**However, the file size must be less than 15 MB to accommodate our email server limit**. Otherwise, please bring your presentation on a USB drive if it is larger than 15 mb. We will have both Microsoft Power Point and Apple Keynote software for your presentations. **Bring your USB drive to the Thursday evening reception if you want to transfer it then.**

2. Poster presenters. The maximum size of the posters is 48” x 48” (120 cm x 120 cm). We will provide push pins to mount your poster on the easels. When you register, your poster will have a number assigned to it that corresponds to the easel number. Please mount your poster on that easel. **Bring your poster to the Thursday evening reception.**

3. Getting to Fort Collins. Those of you who are flying to Denver International Airport can schedule a ride with the **Green Ride Airport Shuttle** service. Please visit its web site (https://greenrideco.hudsonltd.net/) to make arrangements convenient for your flight schedules. There is a Green Ride desk in the main terminal at the airport with employees that can help you find the bus pickup. The bus ride is about 1 hour and 15 minutes. On the web site, in the box “Dropoff location” choose the appropriate destination from the pull-down menu. For those of you staying in the university dormitories it is “FC - Laurel Village”, the Hilton Hotel near campus is “FC - Hilton Ft Collins”, and the University Inn is “FC - Best Western University Inn”. And just to make you aware, afternoon and evening flights into Denver can be rather bumpy!

4. Weather and Climate. Fort Collins has lots of sunshine and is at 5000 ft/1500 meters. If you intend to be outdoors much you should bring sunscreen. We often get afternoon thunder showers in our otherwise dry climate but they are typically not more than an hour or two and it usually clears up afterwards. You may want to bring rain gear or a small umbrella. The current forecast is for the mid to high 80sF/low 30sC.

5. Getting to the UCA. The conference venue is the **University Center for the Arts (UCA)** (attached map, blue box, lower right). Oral and poster presentations will be in this building and directions will be posted inside. After you get settled in Thursday, please come to the UCA for the opening registration and social mixer by 5:30 PM. Walking paths (routes) are noted in blue hatched lines.

A. Laurel Village Alpine Dormitory. Those who are staying in campus housing, walk south to Plum Street and turn east to Meridian Avenue. Take Meridian Avenue south to Pitkin Street and take it east to Mason Street. Cross the railroad tracks and immediately turn right (south) just before the parking garage. Follow the path to just past the parking garage and turn left (east). This path leads to a **tunnel that passes under College Avenue** and comes out at the University Test Gardens (lots of flowers). Continue on this path and it will cross Remington Street to the UCA. **Allow 15-20 minutes to walk**.

B. Hilton Hotel. Proceed from the hotel to Prospect and Centre Avenue at the northwest corner of the Hilton Hotel parking lot. Cross Centre to the west and **take the tunnel under Prospect Avenue**. At Lake Street, turn right (east) to Mason Street. Cross the railroad tracks and immediately turn left (north). Just before the parking garage, turn right (east) and take the path that leads to a **tunnel that passes under College Avenue** and comes out at the University Test Gardens. Continue on this path and it will cross Remington Street to the UCA. **Allow 10 minutes to walk**.

C. University Inn Best Western Hotel. Take Elizabeth Street east to Remington Street (one block). Turn right (south) to Pitkin Street. Once you cross Pitkin Street, the University Center for the Arts is to your left. **Allow 5 minutes to walk.**

6. Registration packet. Your registration packet will include the program, name badge, water bottle and a pass for the Fort Collins MAX bus. The pass allows you to ride the bus through Saturday night. Registration also includes lunch for Friday and Saturday. If you are staying in the dorms you will also have breakfast provided at the dorm dining hall, Corbett Hall, which is just east of Alpine Hall where you are staying (please see the attached map).

If you have questions, please contact me and I will address them. Finally, I will be at the American Society for Virology meeting Saturday through Wednesday so my email access may be intermittent.

Thanks and see you next week.

Tony

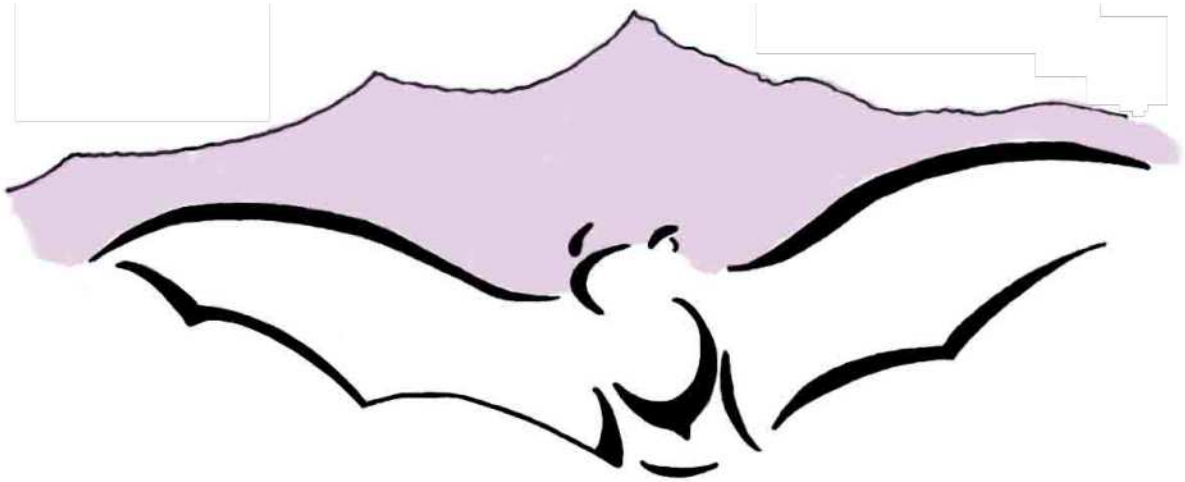
Infectious Diseases of Bats Symposium



June 29-July 1, 2017
University Center for the Arts
1400 Remington St
Colorado State University
Fort Collins, CO 80524

Table of Contents

Program

Venue: **University Center for the Arts**, Colorado State University

Thursday, June 29

5:30 p.m. Registration, PowerPoint file transfer, lobby, **University Center for the Arts**

6:00 p.m. Reception - *Wine, beer and snacks*, **University Center for the Arts**

Friday, June 30

7:00 a.m. Registration, University Center for the Arts

8:00 a.m. Tony Schountz. Colorado State University. **Welcoming remarks**

8:10 a.m. Session I - Filoviruses (Joseph Prescott, Moderator)

8:10 a.m. **Studies of horizontal transmission of Marburg virus among experimentally infected fruit bats**
Jonathan S. Towner[1,2], Amy J. Schuh[1], Brian R. Amman[1], Megan E. B. Jones[1,2], Tara K. Sealy[1], Uebelhoer LS, Spengler JR, Stuart T. Nichol[1]

[1]Viral Special Pathogens Branch, Centers for Disease Control and Prevention, Atlanta, USA, [2]Department of Pathology, College of Veterinary Medicine, University of Georgia, Athens, USA

8:30 a.m. **Investigations of Long-term Protective Immunity against Marburg Virus Reinfection in Egyptian Rousette Bats**
Amy Schuh, Amman BR, Sealy TK, Spengler JR, Nichol ST and Towner JS

Viral Special Pathogens Branch, Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA

8:45 a.m. **Innate immune response to filoviruses and the role of filoviral interferon-inhibiting domains in bat and human cells**
Ivan V. Kuzmin[1,2], Toni M. Schwarz[3], Philipp A. Ilinykh[1,2], Ingo Jordan[4], Thomas G. Ksiazek[1,2,5], Ravi Sachidanandam[6], Christopher F. Basler[3, 7], and Alexander Bukreyev[1,2,5]

Oral Presentation Abstracts

Studies of horizontal transmission of Marburg virus among experimentally infected fruit bats
Jonathan S. Towner[1,2], Amy J. Schuh[1], Brian R. Amman[1], Megan E. B. Jones[1,2], Tara K. Sealy[1], Uebelhoer LS, Spengler JR, Stuart T. Nichol[1]

[1]Viral Special Pathogens Branch, Centers for Disease Control and Prevention, Atlanta, USA, [2]Department of Pathology, College of Veterinary Medicine, University of Georgia, Athens, USA

Objectives: To investigate under experimental conditions the dynamics of Marburg virus replication in a known reservoir host and determine if 1) the virus can be transmitted from infected bats to immunologically naïve bats in the absence of arthropod vectors, and 2) identify the route(s) of virus shedding and therefore likely exposure. **Methods**: Using age-matched captive borne juvenile bats, we inoculated a total of 12 animals with Marburg virus 371 bat isolate and co-housed these animals with 24 naïve contact bats for 9 months under BSL-4 conditions and tested for evidence of virus shedding and transmission. **Results**: Marburg virus shedding was detected in oral, rectal and urine specimens from the inoculated bats through 19 days post infection. During the same time frame, Marburg virus was detected in oral specimens from contact bats, indicating that they were orally exposed to the virus from the inoculated animals. In the late study phase, we found that Marburg virus was horizontally transmitted from the donor bats to naïve contact bats by finding Marburg virus RNA in blood and oral specimens from contact bats, followed by the detection of Marburg virus IgG antibodies in these same animals. **Conclusions**: This study demonstrates, in the absence of any arthropod vectors, 1) direct filovirus transmission from a natural reservoir to another animal, 2) Marburg virus is shed primarily in saliva and urine, and perhaps feces, with some bats acting as super-shedders accounting for more than 80% of the cumulative virus shed, and 3) that this virus/reservoir host system can serve as an bona-fide experimental model for investigating how filoviruses are maintained long-term in nature and what drivers might influence occasional spillover to humans and other animals.

Investigations of Long-term Protective Immunity against Marburg Virus Reinfection in Egyptian Rousette Bats
Schuh AJ, Amman BR, Sealy TK, Spengler JR, Nichol ST and Towner JS

Viral Special Pathogens Branch, Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA

Objectives: The Egyptian rousette bat (ERB; *Rousettus aegyptiacus*) is as a known natural reservoir host for Marburg virus (MARV). Following infection of ERBs with MARV, virus-specific IgG antibodies rapidly decline and by 3 months post infection the bats are MARV seronegative. Therefore, it is unclear whether reinfection plays a role in MARV maintenance. **Methods:** To address this question, ERBs that had been “naturally” or experimentally infected with MARV 17 to 24 months prior were challenged with homologous virus. Following challenge, evidence of MARV replication in the blood and viral shedding from the oral mucosa was monitored for 14 days, MARV IgG antibody responses were monitored for 21 days and tissues obtained at necropsy at 21 days were tested for the presence of MARV RNA. **Results:** No evidence of MARV replication in the blood or shedding from the oral mucosa was detected in either group of bats through 14 days post inoculation. A robust MARV IgG antibody response occurred by seven days post inoculation in all bats, indicating the occurrence of a secondary immune response. **Conclusions:** This study demonstrates that both “natural” and experimental infection of ERBs with MARV induces long-term protective immunity against reinfection and suggests that other factors such as the twice-yearly influx of susceptible juveniles, large colony sizes and population connectivity, drive MARV transmission dynamics in wild populations of ERBs.

Innate immune response to filoviruses and the role of filoviral interferon-inhibiting domains in bat and human cells
Ivan V. Kuzmin[1,2], Toni M. Schwarz[3], Philipp A. Ilinykh[1,2], Ingo Jordan[4], Thomas G. Ksiazek[1,2,5], Ravi Sachidanandam[6], Christopher F. Basler[3, 7], and Alexander Bukreyev[1,2,5]

[1] Department of Pathology, The University of Texas Medical Branch, Galveston, Texas, USA, [2] Galveston National Laboratory, The University of Texas Medical Branch, Galveston, Texas, USA; [3] Department of Microbiology, Icahn School of Medicine at Mount Sinai, New York, New York, USA; [4] ProBioGen AG, Berlin, Germany; [5] Department Microbiology & Immunology, The University of Texas Medical Branch, Galveston, Texas, USA; [6] Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, New York, USA; [7] Current Address: Center for Microbial Pathogenesis, Institute for Biomedical Sciences, Georgia Research Alliance, Eminent Scholar in Virology, Georgia State University, Atlanta, Georgia, USA

Objectives: Innate immune responses in bat (Rousettus aegyptiacus) and human cells to the filoviruses Marburg (MARV) and Ebola (EBOV) were investigated to determine the ability of these viruses to subvert antiviral insults from different host species.
Methods: The innate immune response to filoviruses in bat and humans cells was profiled by deep sequencing and also analyzed by qRT-PCR. Bat mRNAs encoding IFNalpha, beta, gamma, lambda, and interferon stimulated genes (ISG) 54 and 56, were cloned and examined for their antiviral effect in response to MARV and EBOV infection in bat and human cells. Rates of infection and the effects of the major filoviral IFN-inhibiting domains (IID), VP35 and VP24, were analyzed in cells from both host species.
Results: We demonstrated that EBOV and MARV replicate to similar levels in all tested cell lines, indicating that permissiveness for EBOV at cell and organism levels do not necessarily correlate. Filoviruses, particularly MARV, induced a potent innate immune response in rousette cells that was generally stronger than in human cells. Both EBOV VP35 and VP24 IID were found to suppress the innate immune response in rousette cells, but only VP35 IID appeared to promote virus replication. Along with IFN-alpha and IFN-beta, IFN-gamma was demonstrated to control filovirus infection in bat cells but not in human cells suggesting host species specificity of the antiviral effect. The antiviral effects of bat IFNs appeared not to correlate with induction of bat ISG54 and ISG56, which were detected in human cells expressing bat IFN-alpha and IFN-beta.
Conclusions: Rousettus aegyptiacus cells mount robust innate immune responses to filovirus infection. Filovirus IIDs are active in both rousette and human cells; however, the VP35 IID plays a greater role in promotion of viral replication in rousette cells than in human cells. IFN-gamma plays a greater role in control of filovirus infections in rousette non-immune cells than in human cells. At least in part, the antiviral effect of IFN-gamma results from 'cross talk' leading to activation of the type I IFN response. The data are useful for understanding the interactions of filoviruses with natural (Rousettus aegyptiacus) and accidental hosts (humans).

Broad based surveillance for ebolaviruses: PREDICT in Sierra Leone, Liberia, and Guinea
Bird B[1], Goldstein T[1], Anthony S[2], Gbakima A[3], Saylors K[3], Jean Louis F[3], Wolking D[1], Epstein J[4], Karesh W[4], Kreuder-Johnson C[1], Mazet J[1]

One Health Institute UC Davis School of Veterinary Medicine[1], Center for Infection and Immunity Columbia University[2], Metabiota Inc.[3], EcoHealth Alliance[4]

Objectives: Developing and operationalizing strategies to reduce zoonotic pathogen spillover, amplification, and spread are nowhere more relevant than in Sierra Leone, Guinea, and Liberia. The devastating loss of lives associated with the Ebola virus outbreak revealed the urgent need for increased animal and public health sector capacity strengthening. Put into historical context, this epidemic was more than 60 times larger than any previous Ebola outbreak, spread to 7 additional countries, and stretched emergency response efforts to the utmost limits of capacity. **Methods**: PREDICT is working to improve understanding of wildlife reservoirs, spillover hosts, and origins of these viruses; ascertain the potential of virus-spillover into other non-typical hosts, such as livestock or companion animals; gain a greater understanding of high-risk human behavioral activities; and improve disease surveillance and laboratory capacities through workforce development in line with Global Health Security Agenda priorities. **Results**: Due to the impact on these three countries, USAID's PREDICT Project developed a focused effort to better address the threat of ebolaviruses by investigating the virus' animal origins, while strengthening in-country capacity to build and reinforce emerging disease surveillance and detection systems. In each country, teams are conducting concurrent sampling of from multiple animal taxa (dogs, cats, livestock, wildlife) and applying broad based molecular approaches to detect all known and other potential novel ebolaviruses. As of April 2017, over 6,500 animals have been sampled including over 3,500 bats in the three countries, with laboratory testing underway. Without identifying reservoirs of infection and how widely they are distributed across the region, prevention programs to reduce transmission from animals to people will have limited impact, and it is likely that future spillover of ebolaviruses from animals into humans will continue to occur. **Conclusions**: As we have seen over the years in Central and Eastern Africa where filovirus outbreaks have repeatedly occurred, effective control of these rare "spillover" events is possible and, when the right technical capacities are in place, these outbreaks can even be limited to a small number of human cases.

Quantifying signatures of resistance and tolerance to filoviruses in bat cell lines
Cara E. Brook[1], Melinda Ng[2], Esther Ndungo, Rohit K. Jangra, Andrew P. Dobson, Andrea L. Graham, Bryan T. Grenfell, C. Jessica E. Metcalf[1]*, Kartik Chandran[1]*

[1]Department of Ecology and Evolutionary Biology, Princeton University;
[2]Department of Microbiology and Immunology, Albert Einstein College of Medicine
*These senior authors contributed equally to this work.

Objectives: Previous work has demonstrated that a single amino acid change in the filovirus receptor, NPC1, in *Eidolon helvum* cells make them refractory to Ebola virus infection, hinting at a possible coevolutionary history between virus and bat host. We sought to expand on this nascent evidence of the evolution of pathogen resistance. **Methods:** We carried out a series of plaque assays, in which we challenged bat (EidNi/41.3, RoNi/7.1, PaKiT01), U2OS, and Vero cell lines with multicycle replicating pseudotype Ebola and Marburg filoviruses. Because of the agar overlay inherent to the plaque assay, viral transmission was restricted to neighboring cells. We visualized this transmission by photographing the timecourse of infection spread across the cell monolayer, and processing the images to quantify the proportion infected at a given time point as the proportion of photograph illuminated by GFP-tagged virus. We then fit spatially-structured traditional epidemiological models to the resulting data, in order to disentangle the mechanisms underpinning diverse trajectories of tolerance and resistance in different virus-cell line relationships. **Results:** Our modeling highlights diverse, species-specific evolutionary relationships between particular bat cell lines and particular filoviruses, which necessitate mechanisms of pathogen resistance in order to recapture data trajectories in some cases (chiefly *E. helvum* and Ebola and *P. alecto* and Marburg) and mechanisms of tolerance in others. **Conclusions:** Our work highlights the power of interdisciplinary approaches, combining quantitative epidemiology with cell biology and adds to growing evidence suggestive of unique species-specific coevolution between bats and filoviruses.

Serologic evidence of exposure to filoviruses in fruit bats, Singapore
Laing ED[1], Mendenhall IH[2], Linster M[2], Low DHW[2], Chen Y[2], Yan L[1], Sterling SL[1], Borthwick S[2], Neves ES[2], Lim JSL[2], Skiles M[2], Lee BPY[4], Wang LF[2], Broder CC[1], Smith GJD[2, 5]

Uniformed Services University, Bethesda, MD, USA[1], Duke-National University of Singapore Medical School, Singapore[2], North Carolina State University, Raleigh, NC, USA[3], National Parks Board, Singapore[4], Duke Global Health Institute, Duke University, Durham, North Carolina, USA[5]

Objectives: Bats are known natural hosts of Nipah virus and Maburg virus, and the collective evidence suggests that bats are also the natural hosts of ebolaviruses. Reston virus, an *Ebolavirus* species, is known to circulate in species of bats in the Philippines. To examine whether ebolaviruses and marburgviruses are more broadly present in Southeast Asia, we tested sera from three fruit bat species endemic in Singapore and widely distributed throughout Southeast Asia for evidence of past exposure to known species of ebolaviruses and marburgviruses. **Methods:** Sera were collected from the above-mentioned bat species from 2011 to 2016 in Singapore to screen for evidence of exposure to filoviruses. Venous blood was diluted 1:10 in 1×PBS and tested using a Bio-Plex® bead-based multiplex assay that simultaneously probes sera for immunoglobulins specific to the viral envelope glycoprotein from representative strains of all previously described *Ebolavirus* and *Marburgvirus* spp. We employed methods developed by Peel AJ *et al.* to establish a median fluorescence intensity (MFI) cutoff value. We screened 409 samples with this *Ebolavirus/Marburgvirus* spp. Bio-Plex® assay. **Results:** Positive results indicated that bats were previously infected with viruses related to the ebolaviruses from which the virus surface proteins were derived. Of the species tested, 10% of *Eoncyteris spelaea*, 8% of *Cynopterus brachyotis*, and 4% of *Penthetor lucasi* had positive sera results for antibodies specific to ebolaviruses.
Conclusion: These serological results demonstrated that viruses related to ebolaviruses have previously infected all three species of fruit bats, and may circulate in the populations, but we have not detected the virus in any samples. We conducted next generation sequencing on urine and feces, bat cell lines and screened numerous samples from bats in Singapore and have detected no evidence of the virus. As there is no evidence of Ebola virus disease in humans in Singapore or Southeast Asia, we think that these serological findings are evidence of novel, yet undescribed viruses related to known ebolaviruses.

Predicting undiscovered filovirus reservoirs and patterns of disease emergence
David Hayman[1]

[1]Molecular Epidemiology and Public Health Laboratory, Hopkirk Research Institute, Massey University, New Zealand

Objectives: How can we discover unidentified filovirus hosts and where should we be searching for the viruses? Filoviruses *Ebolavirus* (EBOV) and *Marburgvirus* cause hemorrhagic fevers with high mortality rates, posing significant threats to public health and wildlife conservation. The viruses have sporadically emerged over the last 40 years at least, and yet the hosts of EBOV in particular remain poorly known and characterized. Here different studies help inform field surveillance through the identification of bat traits that predict filovirus reservoirs and ecological processes that facilitate emergence. **Methods:** Different modeling approaches were used. A mathematical model with seasonal birthing synthesized filovirus and bat data to determine if biannual birthing

might facilitate pathogen persistence. Regression analyses on serological data tested the model predictions. A machine learning approach provided additional information on bats, integrating multiple host trait data. Fragmentation analyses using satellite land cover data and Ebola virus disease outbreak index cases in humans (i.e. spillover from wildlife reservoirs) tested the hypothesis that forest fragmentation was correlated with emergence. **Results:** Synthesis of filovirus and bat data through models suggests bi-annual breeding and longer incubation periods, such as reported for Egyptian fruit bats and EBOV in experimental studies, allow viral persistence in bat colony sizes often found in nature. Serological data and machine learning approaches support the findings, with bats from species with two annual birth pulses more likely to be seropositive (odds ratio 4.4, 95% confidence interval 2.5-8.7) than those with one, suggesting biannual birthing may allow filovirus persistence. Machine learning algorithms suggest species' geographic range overlap may facilitate filovirus persistence. Finally, fragmentation analyses suggest Ebola virus disease outbreaks occurred mostly in hotspots of forest fragmentation. **Discussion:** These analyses suggest surveillance for filoviruses, especially ebolaviruses, might be targeted to young bats from species with biannual birthing in areas of fragmented forested habitat. The link between forest fragmentation and EBOV outbreaks suggests there is common ground between biodiversity conservation and disease risk mitigation. Together these results will help the research community identify where, when and in which species to continue the search for filovirus hosts.

Bats as possible animal origin of MERS-CoV

Susanna K. P. Lau

Department of Microbiology, The University of Hong Kong, Hong Kong, China

Objectives: Bats are important reservoir for emerging viruses including coronaviruses. Although dromedary camels are believed to be the immediate animal source of the recent MERS epidemic, the evolutionary origin of MERS-CoV remains obscure. While horseshoe bats are the primary reservoir of ancestors of SARS-CoV, the possible role of bats in the emergence of MERS-CoV is less clear. When MERS-CoV was first discovered, it was found to be most closely related to *Tylonycteris* bat CoV HKU4 (Ty-BatCoV HKU4) and *Pipistrellus* bat CoV HKU5 (Pi-BatCoV HKU5) previously discovered in lesser bamboo bat (*Tylonycteris pachypus*) and Japanese pipistrelle (*Pipistrellus abramus*) respectively in Hong Kong. Subsequently, two other lineage C betacoronaviruses, BtVs-BetaCoV/SC2013 and Coronavirus Neoromicia/PML-PHE1/RSA/2011 (NeoCoV) were also detected in bats from China and Africa respectively. Interestingly, a lineage C betacoronavirus, Erinaceus CoV VMC/DEU, has also been found in European hedgehogs, which are phylogenetically closely related to bats, in Europe. Although NeoCoV represents the closest bat counterpart of MERS-CoV in most genome regions, the spike (S) protein, important for host receptor binding, is genetically divergent from that of MERS-CoV. On the other hand, Ty-BatCoV HKU4 possessed an S protein being most closely related to MERS-CoV. The spike of Ty-BatCoV HKU4, but not that of Pi-BatCoV HKU5, was able to utilize the MERS-CoV receptor, human dipeptidyl peptidase 4 (hDPP4) or CD26, for cell entry. These findings suggested that bats may be the primary host of the ancestor of MERS-CoV. **Methods**:To better understand the evolutionary path of MERS-CoV, we collected bat samples from various regions in China. **Results**: Diverse CoVs were detected, including a potentially novel lineage C betacoronavirus. Compared to Ty-BatCoV HKU4 and Pi-BatCoV HKU5, the virus was even more closely related to MERS-CoV and NeoCoV in most regions of its genome. In contrast, the S1 region was less closely related MERS-CoV than Ty-BatCoV HKU4 but more closely related to MERS-CoV than Pi-BatCoV HKU5. To determine if this virus can utilize hDPP4 as receptor, binding experiments using S1-receptor-binding domain (RBD), cell entry studies using pseudovirus assays and structural modelling of the RBD-hDPP4 interphase were performed. **Conclusions**: The results suggested a stepwise evolutionary process among lineage C betacoronaviruses in gaining the ability to bind hDPP4, and support a bat origin of MERS-CoV.

Rapid detection of MERS coronavirus ancestors in bats

Prof. Patrick CY Woo, Department of Microbiology, The University of Hong Kong, Hong Kong.

Objectives: Since its first appearance in 2012, the Middle East Respiratory Syndrome (MERS) has affected more than 25 countries in four continents with more than 1,300 cases and a high fatality rate of more than 30%. A novel lineage C betacoronavirus (betaCoV), MERS-CoV, has been confirmed to be the etiological agent. Human dipeptidyl peptidase 4 (hDPP4) was found to be the cellular receptor for MERS-CoV. Subsequent detection of MERS-CoV and its antibodies in dromedaries in various countries in the Middle East and North Africa have implied that these animals are probably the reservoir for MERS-CoV. Other lineage C betaCoVs in bats [e.g. *Tylonycteris* bat CoV HKU4 (Ty-BatCoV-HKU4), *Pipistrellus* bat CoV HKU5 (Pi-BatCoV-HKU5)] and hedgehogs were found to be closely related to MERS-CoV. So far, detection of MERS-CoV and discoveries of its closely related CoVs are most efficiently achieved through RT-PCR. Although RT-PCR is highly sensitive, its turn-around-time is about four hours and the test requires expensive equipment, stringent laboratory set-up and personal attention to prevent laboratory PCR product cross contamination which may lead to false-positive results.

Methods: Recently, we have developed a monoclonal antibody-based rapid nucleocapsid protein (NP) detection assay for on-site diagnosis of MERS-CoV, which can be finished in 30 minutes. **Results and Conclusions**: This rapid test is highly specific for MERS-CoV for human and dromedary samples, as samples containing other human CoVs (HCoV-OC43, HCoV-229E, HCoV-NL63 and HCoV-HKU1) or dromedary CoV UAE-HKU23 all showed negative results. However, we hypothesize that the rapid test can pick up betaCoVs closely related to MERS-CoV; and hence would be useful for the discovery of MERS-CoV ancestors. To test this hypothesis, we examine the usefulness of this rapid test to detect four alphaCoVs and four lineage B, C and D betaCoVs in fecal samples of bats.

Global patterns in coronavirus diversity

Objectives: Since the emergence of SARS-CoV and MERS-CoV it has become clear that bats are important reservoirs of coronaviruses (CoVs). Despite this, only 16% of all CoV sequences in Genbank come from bats. The remaining 84% largely consist of known pathogens of public health or agricultural significance, indicating that current research effort is heavily biased towards describing known diseases rather than the 'pre-emergent' CoV diversity circulating in bats. Our study addresses this critical gap, and focuses on the evolutionary and ecological drivers of CoV diversity in resource poor countries, where the risk of zoonotic emergence is believed to be highest. **Methods**: We surveyed the diversity of CoVs in multiple host taxa from 20 countries in Africa, Asia and Latin America to explore the factors driving viral diversity at a 'global' scale. Partial CoV sequences were identified using consensus PCR, which was chosen in part because it could be easily implemented in resource poor settings. Sequences were then parsed into phylogenetic clusters (operational taxonomic units) and analyzed using ecological and epidemiologic approaches. **Results**: In total we identified sequences representing 100 discrete clusters, 91 of which were found in bats, and showed that patterns of CoV diversity correlate with those of bat diversity. This cements bats as the major evolutionary reservoirs and ecological drivers of CoV diversity. Preliminary co-phylogenetic reconciliation analysis indicated that frequent host switching has contributed to CoV evolution, and that regional variation exists in the dynamics of this process. **Conclusions**: Overall our study represents a model for exploring global viral diversity and advances our fundamental understanding of CoV biodiversity and the potential risk factors associated with zoonotic emergence.

SARS coronavirus may have originated from frequent recombination events between SARS-like coronaviruses in a single horseshoe bat habitat

Ben Hu[1], Lei-Ping Zeng[1], Xing-Lou Yang[1], Xing-Yi Ge[1], Wei Zhang[1], Bei Li[1], Dong-Sheng Luo[1], Yun-Zhi Zhang[2], Mei-Niang Wang[1], Peter Daszak[3], Lin-Fa Wang[4], Jie Cui[1], Zheng-Li Shi[1]

Objectives: Horseshoe bats are recognized as the natural reservoirs of Severe Acute Respiratory Syndrome coronavirus (SARS-CoV), as an increasing number of SARS-like coronaviruses (SL-CoV) have been detected in this bat family since 2005. However, knowledge gaps remain between currently known bat SL-CoVs and the direct progenitor of SARS-CoV. Further information is needed to better understand where and how SARS-CoV originated from bat reservoirs. **Methods:** We have conducted a 5-year surveillance of SL-CoV in a cave inhabited by horseshoe bats in Yunnan, China. Full-length genome sequencing of 11 novel bat SL-CoVs discovered in this single location was performed and genomic characterization, phylogenetic analysis and recombination analysis were conducted. Efficiency of human ACE2 usage was also evaluated in HeLa cells for several newly identified strains. **Results:** Our findings revealed that genetically diverse bat SL-CoVs were circulating in this single location, including different strains with high sequence similarity to SARS-CoV in the highly variable N-terminal

domain (NTD) and receptor-binding domain (RBD) of S protein and the ORF8 region, respectively. Meanwhile, compared with other SL-CoVs, strains identified from this cave exhibited higher sequence similarity to SARS-CoV in the non-structural proteins. Evidence supported that frequent recombination events have occurred within the S gene and around ORF8 between bat SL-CoVs in this cave and may have promoted the generation of the pandemic SARS-CoV. Cell entry studies demonstrated that different newly identified SL-CoVs with variants of S protein are all able to use human ACE2 as the receptor, which represent a potential risk of emergence if given the opportunity to spillover. **Conclusions:** We have identified an epicenter of SL-CoVs where the director progenitor of SARS-CoV likely originated via sequential recombination events. These findings offered important new insight into understanding the geographical and evolution origin of SARS-CoV and highlights the need to pursue the surveillance of bat SL-CoVs to make better preparation for future emergence of SARS-like disease in humans.

A metagenomic approach identifying a MERS-related coronavirus in a bat from South Africa

Marike Geldenhuys[1], Marinda Mortlock[1], Jaqueline Weyer[2], Oliver Bezuidt[3], Ernest Seamark[4], Teresa Kearney[5,6], Cheryl Gleasner [7], Tracey Erkkila[7], Helen Cui[7] and Wanda Markotter[1]

[1]Centre for Viral Zoonosis, Department of Medical Virology, Faculty of Health sciences, University of Pretoria, Pretoria, South Africa; [2]Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, South Africa; [3]Centre for Microbial Ecology and Genomics, University of Pretoria, Pretoria, South Africa; 4AfricanBats NPC, South Africa and Centre for Wildlife Management, University of Pretoria, Pretoria, South Africa; [5]Animal, Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa; [6]Ditsong Museum of Natural History, Pretoria, South Africa; [7]Los Alamos National Laboratory, New Mexico, USA

A Middle East Respiratory Syndrome (MERS) related coronavirus was previously detected in a Cape serotine bat (*Neoromicia capensis*) from the KwaZulu Natal Province in South Africa. Though the virus showed significant similarity to human MERS coronavirus (MERS-CoV), it was too divergent to be considered the direct progenitor of the virus causing human MERS-CoV outbreaks. **Objectives:** As part of a broader viral discovery surveillance program investigating excreted zoonotic viruses from bats, we implemented metagenomic techniques to collectively screen the virome of 60 *Neoromicia* bats constituting 6 species from 4 South African provinces sampled from 2007-2015. **Methods:** Using a viral particle enrichment methodology, total nucleic acids from faecal and rectal specimens were sequenced on Illumina's MiSeq and NextSeq500. Coding complete genome sequencing was performed with further amplicon sequencing on Illumina's MiSeq. Bayesian (BEAST) phylogenetic comparisons and pairwise estimations were performed with full genome representatives of all 4 betacoronavirus lineages. **Results:** We detected a MERS-related betacoronavirus from the same *Neoromicia* species. The virus shared a 97.2% overall nucleotide identity to another *Neoromicia* MERS-related virus identified in South Africa, and 85.5-85.6% nucleotide identity to human and camel (alternative hosts) strains of MERS-CoV. Significant discrepancies between bat-borne and human/camel MERS-CoV genomes were attributed to the low (63.7-64.3%) amino acid similarities of the spike genes, which is responsible for receptor attachment. Genome comparisons between betacoronavirus lineages of emerging viruses, namely MERS-CoV and the equivalent Severe Acute Respiratory Syndrome (SARS) coronaviruses, indicate that the relative phylogenetic distances between *Neoromicia* MERS-related strains and human/camel MERS-CoV are far greater than the distances between SARS-related bat viruses and human SARS viruses. **Conclusions:** Continued surveillance within the *Neoromicia* genus may yield additional MERS-related viruses sharing greater similarity to the human and camel MERS strains (as was shown with detected SARS-related bat viruses). Alternatively, if the progenitor of MERS-CoV originated from the *Neoromicia* genus, the currently identified diversity would suggest that significant receptor adaptation was required within dromedary camels (or unknown intermediate hosts) prior to being transmitted to humans. Continued viral surveillance in regions inhabited by both these hosts may aid in understanding the emergence of MERS.

New insights into the antiviral innate immune response of *Desmodus rotundus*

Sarkis Sarkis, Marie-Claude Lise, Edith Darcissac, Stéphanie Dabo, Christine Neuveut, Benoît de Thoisy, Eliane Meurs, Anne Lavergne and Vincent Lacoste

Institut Pasteur de la Guyane

The common vampire bat, *Desmodus rotundus*, is the main reservoir of rabies virus in South America. Mechanisms that allow persistence of viruses in bats are not well-defined. During the last decade, innate immunity has emerged as one of the implicated mechanisms. As a non-model organism, no tools were available regarding *D. rotundus*, there was therefore a crying need for characterizing their immune system. Given that the interferon (IFN) system provides the first line of defense upon viral recognition, we investigated the IFN-I response in an immortalized cell line, established from a *D. rotundus* embryonic lung, stimulated with synthetic

dsRNA (poly I:C). We observed that stimulation induced high levels of expression of all PRRs involved in dsRNA recognition, as well as a rapid up-regulation of both IFN-α1 and β. Furthermore, in characterizing some of the ISGs such as OAS1, PKR and ADAR, we identified two OAS1 genes, tentatively named *OAS1a* and *OAS1b*. Upon stimulation, *OAS1b* appeared to be the most inducible ISG tested. These results not only provide evidence of the intact signaling pathway of the IFN-I in our cellular model, but also that *OAS1b* may be a major player in antiviral activity in *D. rotundus*. In the frame of the present work, we generated a sum of insightful tools specific of the common vampire bat useable to the study of a number of different viruses, the first of which is the rabies virus.

A comparative study of the autophagy pathway during virus infection of bat (natural) and human (accidental) host cells

Eric D. Laing[1], Spencer L. Sterling[1], Dawn L. Weir[1], Sasha E. Larsen[2], Linfa Wang[3], Brian C. Schaefer[1], and Christopher C. Broder[1]

[1]Department of Microbiology, Uniformed Services University, Bethesda, MD, USA; [2]Department of Pharmacology, Uniformed Services University, Bethesda, MD, USA; [3]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore

Objectives: In contrast to other terrestrial animals, infection of bats with ebolaviruses and henipaviruses does not cause symptomatic disease. Whether bats have antiviral mechanisms to control these infections or how these viruses persist at a cellular level is largely unknown. Autophagy is a cellular protein homeostatic process, which has been implicated as a cell-autonomous innate defense mechanism against a broad array of intracellular infections. Bats are longer lived compared to other similarly sized mammals and increased proteostatic processes have been observed in long-lived mammalian species. **Methods:** In this study, we performed an investigation of autophagy in cell lines from the black flying fox (*Pteropus alecto*), a natural host of Hendra virus and Australian bat lyssavirus (ABLV), and human cells. ABLV, a neurotropic virus, was used as a model bat-borne virus to examine the interactions between an intracellular virus infection and autophagy in host cells. **Results:** Autophagy activation was observed in *P. alecto* brain tissue-derived primary and secondary cells infected with replication competent ABLV 1 and 2 days post infection. Compared to a human neuroblastoma cell line, *P. alecto* kidney and brain cells exhibited a higher level of basal autophagy. Treatment of bat and human cell lines with pharmacological activators of autophagy reduced ABLV replication. Quantification of ABLV titers and protein levels after infection of bat and human cells lines demonstrated that bat cells were less permissive to ABLV infection. Lentiviral knockdown of autophagy-related gene-5 (ATG-5) in bat and human cell lines did not result in a significant silencing of the autophagy pathway, however, a trending increase of ABLV replication levels was observed in the ATG-5 knockdown cells. Pre- and post-infection treatment of human neuroblastoma cells with BEZ235, an mTOR- and PI3K-inhibitor, significantly decreased virus replication in a dose-dependent manner. **Conclusions:** To our knowledge this is the first study to explore whether the autophagy pathway has a role as an antiviral defense mechanism during virus infection in bats. Ongoing experiments aimed at the interplay between autophagy and apoptosis will be critical to supporting our hypothesis that autophagy is an antiviral defense mechanism in bats.

Development of a minimally invasive individual identification technique for continuous monitoring of African bat species

Stewart McCulloch[1]; Teresa Kearney[2,3,4]; Ernest Seamark[3,5]; Janusz Paweska[6]; and Wanda Markotter[1]
[1] Centre for Viral Zoonoses, Department of Medical Virology, Faculty of Health Sciences, University of Pretoria, South Africa; [2] School of Animal, Plant and Environmental Sciences, University of Witwatersrand, Private Bag 3, Wits 2050, South Africa [3] AfricanBats, 357 Botha Ave, Kloofsig, 0157, Pretoria, South Africa; [4] Ditsong National Museum of Natural History, Pretoria, South Africa; [5] Centre for Wildlife Management, Faculty of Natural and Agricultural Sciences, University of Pretoria, South Africa, 0001; [6] Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, Johannesburg, South Africa.

Objectives; An ever increasing number of potentially zoonotic diseases are associated with bat populations throughout the world, and as such the continuous monitoring and surveillance of these populations has become essential, not only for disease epidemiology but also in order to address the lack of knowledge available for biology, ecology and life histories of the majority of bat species. This requires the development of an ethically acceptable, cost effective, durable and reliable marking system to facilitate monitoring of individual bats. In order to address annual population structure, potential movement patterns and individuals' infection or exposure status we tested the ability to uniquely mark 11 bat species from six families, ranging in mass from 4g to 120g, using wing tattoos. Specific serological monitoring of Lagos bat virus exposure in *Rousettus aegyptiacus,* focussing on the presence and duration of neutralising antibodies has been undertaken since 2012. **Methods;** Non-toxic black ink was applied into the interdermal layers of the propatagial membrane of the bat by means of a tattoo system with nine-pronged needles. The tattooing procedure was performed on individual bats from a captive colony of *R.*

aegyptiacus (n=287) and free-flying, wild populations of the aforementioned species (n=2559). The robustness and longevity of this system was assessed from recaptures of tattooed individuals representing four of the above species in the wild, and observations of the captive colony of *R. aegyptiacus*. **Results;** This technique provides a simple, durable and cost effective marking system for both immediate and medium term monitoring, with no observed detrimental effects to the individuals to date. The longest periods between application and observation of tattoos has been; 927 days for *R. aegyptiacus*, 292 days for *N. thebaica*, 126 days for *M. natalensis* and 89 days for *Rh. smithersii.* Over 100 *R. aegyptiacus* recapture events have demonstrated individuals' seroconversion, antibody maintenance and loss against LBV. **Conclusion;** This technique has shown potential to facilitate monitoring individual bats' infection or exposure status in both captive and wild settings, with individual seroconversion and titer loss against LBV being observed, as well as providing an effective mark-recapture identification for population and movement studies.

Characterization of a novel Rhabdovirus isolated from insectivorous bat (*Pipistrellus kuhlii*) in Italy
Davide Lelli[1], Alice Prosperi[1], Chiara Chiapponi[1], Paola Debenedictis[2], Anna Maria Gibellini[3], Stefania Leopardi[2], Enrica Sozzi[1], Dino Scaravelli[4], Ana Moreno[1], Antonio Lavazza[1]

[3]Wildlife Rehabilitation Center WWF of Valpredina via Pioda n.1, 24060 Cenate Sopra(BG), Italy
[4]University of Bologna, Department of Veterinary Medical Sciences, via Tolara di sopra 50 - 40064 Ozzano Emilia (BO), Italy

Objectives: *Rhabdoviridae* is one of the most ecologically diverse families of RNA viruses with clinical importance. Herein we report the isolation and the genome characterization of a novel rhabdovirus detected from a bat collected within a survey implemented in Italy on emerging viruses of bats. **Methods:** A fresh carcass of an adult female of *Pipistrellus kuhlii* spontaneously dead in a wildlife rehabilitation center in Northern Italy was fully necropsied. Tissue samples from different organs (lung, hearth, intestine) were subjected to viral isolation on cell culture. Virus identification was performed using negative staining electron microscopy (nsEM) and NGS sequencing. Molecular and phylogenetic analyses were performed. **Results:** Anamnesis reported sensory depression, inappetence, normal body mass and injuries of patagium consistent with a cat bitten. The death occurred three days after the admission to the rehabilitation center and no pathological lesions indicative of infectious diseases were observed at necropsy. CPE was observed on VERO cells inoculated with a pool of organs and nsME performed on cells supernatants revealed characteristic bullet-shaped viral particles referable to rhabdovirus. Tests aimed to exclude rabies and related lyssaviruses resulted negative. The complete genome size was 11,780 nt comprised 5 genes encoding the canonical rhabdovirus structural proteins and an additional transcriptional unit (U1) encoding a small protein (157 aa) located between the G and L genes (3'-N-P-M-G-U1-L-5'). BLAST analysis showed the highest nucleotide identity (65%) to Le Dantec virus (LDV) (human, 1965 Senegal) the prototype strain of the putative genus Ledantevirus. The most highly conserved protein L shared 70% and 69% of aa identity with LDV and Keuraliba virus (KEUV) (gerbil, 1968 Senegal) respectively. Phylogenetic tree based on full-genome sequence confirm the belonging of the new isolate to the ledantevirus group. **Conclusions:** A novel rhabdovirus was identified from *Pipistrellus kuhlii*, the most common species in urban areas in Italy. This finding represents (beside lyssaviruses) the only bat-borne rhabdovirus isolated in Europe. Specific diagnostic tools for viral detection will be set up for epizootiological investigations aimed to define the viral ecology and diffusion in bats population in Italy, in order also to further characterize and clarify its zoonotic potential.

Age-specific dynamics of maternally- and infection- derived immunity within African bat populations
Alison J Peel[1], Kate S Baker[2], David TS Hayman[3], Andrew A Cunningham[4], James LN Wood[5], Romain Garnier[5] and Olivier Restif[5]

[1] Environmental Futures Research Institute, Griffith University, Nathan, QLD, Australia; [2] Institute for Integrative Biology, University of Liverpool, UK; [3] Molecular Epidemiology and Public Health Laboratory, Hopkirk Research Institute, Massey University, Palmerston North, New Zealand; [4] Institute of Zoology, Zoological Society of London, Regent's Park, London, UK; [5] Department of Veterinary Medicine, University of Cambridge, Cambridge, UK

Objectives: Predicting and managing spillover of emerging infectious diseases to domestic animals and humans depend on data on reservoir host distribution, ecology and immunology as well as the mechanisms governing pathogen transmission among its populations. However, such data are generally sparse. This is exemplified by old-world fruit bats, which have been linked to an increasing number of zoonotic viruses, but whose ecology is

challenging to study and immunology has only recently begun to be elucidated. Even where appropriate data are available, fission-fusion population structures make it challenging to separate out the dynamical effect of pathogen reintroduction into the study population through movement from the transmission dynamics expected within a closed population. Island populations provide ideal natural experiments and involve simplifications analogous to the assumptions often made in modelling studies (e.g. single, closed population of a single species), allowing exploration of underlying processes. Here, building on an extensive body of work on straw-coloured fruit bats (*Eidolon helvum*), we aim to further elucidate fundamental processes governing viral dynamics, including the role of maternally-derived antibodies (MatAb). **Methods:** We focus on two viruses for which *E. helvum* is a reservoir (Lagos bat virus (LBV) and African henipavirus) and look for evidence of the presence of MatAb in wild *E. helvum* from continental and island populations. We use rare age-specific data to model waning rates of maternally- and infection- derived antibodies. These results then informed the parameterisation of a stochastic seasonal birth model to explore population-level persistence in the presence of MatAb, in both naive and non-naive populations. **Results:** Statistical modelling supported age as the strongest determinant of seroprevalence for both henipavirus and LBV, in addition to highly significant correlations between mother-offspring pairs. Age-specific seroprevalences predicted rapid loss of maternal immunity and effectively lifelong infection-induced immunity (particularly for LBV). The inclusion of MatAb had considerable implications on viral persistence within populations in a dynamic birth pulse model. **Conclusions:** This study helps to better understand endemic viral dynamics in bat populations, and the implications of considering the presence of MatAb in broader wildlife disease systems.

Detection of rubula- and related viruses in an Egyptian fruit bat (*Rousettus aegyptiacus*) colony in South Africa

Marinda Mortlock[1], Jacqueline Weyer[2], Janusz Paweska[2] and Wanda Markotter[1]

[1]Centre for Viral Zoonoses, Department of Medical Virology, Faculty of Health Science, University of Pretoria, South Africa; [2]Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, Johannesburg, South Africa

Objectives: More than 22 viral families have been associated with bats globally, eight of which with the Egyptian fruit bat (*Rousettus aegyptiacus*) occurring across sub-Saharan Africa and parts of the Middle East. Among numerous other zoonotic viruses, this species has also been associated with zoonotic henipaviruses (family *Paramyxoviridae*). More recently, a newly described zoonotic rubulavirus, Sosuga virus, was detected in this species from Uganda. The occurrence and diversity of these viruses remain unknown in Southern Africa. **Methods:** A broadly reactive hemi-nested RT-PCR assay targeting the *Avula-Rubulavirus* genera within the *Paramyxoviridae* family was used for nucleic acid detection. Spleen and kidney samples from bats collected during 2012-2016 from a cave in the Limpopo Province of South Africa, were retrospectively screened for the presence of rubulavirus RNA. Virus isolation, next-generation Illumina sequencing and amplicon sequencing were used to obtain full gene or genome sequences for comparison. **Results:** A total number of 137 bats were screened of which 5.84% of spleen samples tested positive. We detected several rubulavirus-related viruses grouping in a sister clade to the *Rubulavirus* genus. This clade contains other bat-associated rubulaviruses including the zoonotic Sosuga virus. Additionally, a co-infection with a virus closely related to human mumps virus was detected in one of the bats sampled. Preliminary results also suggest seasonality of these viruses in the colony, as positive individuals were predominantly detected in winter months. This phenomenon coincides with the loss of maternal antibodies i.e. an influx of susceptible individuals into the colony. **Conclusion:** The first evidence of bat-associated rubulaviruses from *R. aegyptiacus* in South Africa, some of which are related to know human pathogens, are reported. Additionally, a considerable diversity was detected from a small sample size. Enhanced surveillance might shed light on the prevalence of these viruses within the targeted colony. Considering the potential excretion of these viruses during the winter months might be the next step in determining their transmission potential. This is of importance as the specific cave is situated within a rural settlement surrounded by free-roaming livestock and is frequented by humans for religious practices.

Influenza-like virus and paramyxovirus screening in Brazilian bats

Angélica Cristine Campos[1]; Luiz Gustavo Góes[1]; Cristiano Carvalho[2]; Guilherme Ambar[5]; Luciano M. Thomazelli[1]; Jhiovana Cristielly Costa[1]; Mariana Cristine de Souza[1]; Adriana Ruckert[3]; Débora C. Oliveira[3]; Luzia F. Martorelli[3]; Ana Paula Kataoka[3]; Marcelo S. Nardi[4]; Juliana L. Summa[4]; Roberta Marcatti de Azevedo[4]; Wagner A. Pedro[2]; Luzia H. Queiroz[2]; Ariovaldo P. Cruz-Neto[5] and Edison Durigon[1]

do Município de São Paulo, São Paulo-SP; [5] Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista (UNESP), Rio Claro-SP

Objectives: Bats are recognized as natural reservoirs of emergent viruses related to severe human disease outbreaks including Rabies, Nipah, Hendra and SARS coronavirus. Since the discovery of Hendra and Nipah emergent paramyxovirus in late 1990s in flying foxes bats from Australia and Asia, others bat-borne paramyxovirus have been identified in bats across the globe including bats species from Australia, Asia, Africa and America. Recently, new members of the influenza A virus where detected in bats from Guatemala and Peru, amplifying the host variety of Influenza virus A group. Despite the recent detection of Influenza-A and Paramyxovirus in South American bats and the spill-over events of paramyxovirus from bats to humans only few studies had analyzed the occurrence of influenza-like virus and paramyxovirus in Brazilian's bats. These study aims to analyze the occurrence and diversity of influenza-like virus and paramyxovirus in Brazilian bats. **Methods:** A total of 1071 samples including distinct tissues (intestine, lung, kidney and spleen), rectal and oral swabs, and serum (821 individuals/47 species) from urban area and Atlantic Forest biome were analyzed. The Total Nucleic Acid was extracted and cDNA synthesis was performed. Samples were screened by Pan-Flu PCR assay targeting the Influenza PB1 gene and by a Semi-Nested Pan-paramyxovirinae PCR assay targeting the L gene. **Results:** PCR fragments for both assays were observed in electrophoresis analysis. The amplicons were purified and sequenced by Sanger method. Sequencing confirmed the presence of 3 distinct Paramyxovirus lineages in eight bats. Morbillivirus-like was detected in insectivorous bat's *Molossus rufus* (intestine) and *Myotis nigricans* (lung)*;* Unclassified Paramyxovirus and one possible Henipa-like virus was found in hematophagous bats *Desmodus rotundus* in kidney samples*.* **Conclusions:** This study report the lack of detection of influenza-like in a high number of bat samples and may indicate the absence or the lower prevalence of these virus group in bats from Brazil. Our results also suggest the presence of paramyxovirus genotypes in bats commonly found in rural and urban area, including a probably Henipa-like virus in hematophagous bats, species that already had been described as vectors of rabies and others paramyxovirus with unknown zoonotic potential.

Hendra virus dynamics and spillover

Raina Plowright[1], Maureen Kessler[1], Alison Peel[2], Hamish McCallum[2], Peggy Eby[3]

[1]Department of Microbiology and Immunology, Montana State University; [2]Environmental Futures Research Institute, Griffith University, Queensland, Australia; [3]University of New South Wales, Australia.

Hendra virus provides a model system for understanding the dynamics of emerging bat viruses and spillover. One factor constraining our ability to study Hendra virus spillover is the limited knowledge of the biology of the virus within its reservoir hosts. We present three different hypotheses for how within-host pathogen dynamics in bats may interact with among host factors to drive dynamics of emerging bat virus spillover. These hypotheses include: pulsed viral excretion due to seasonal epidemics, local persistence due to waning immunity within bats, or episodic shedding from persistently infected bats. We discuss the evidence for each hypothesis and show that differentiation among these scenarios is essential for predicting and managing spillover.

Using serology to understand the dynamics of concurrent viral infections in pteropid bats

Jonathan H. Epstein[1], Noam Ross[1], Ariful Islam[1], Dan Crowley[1,2], Gary Crameri[3], Christopher Broder[4], Linfa Wang[5], and Peter Daszak[1].

[1]EcoHealth Alliance, NY USA; [2]Columbia University Mailman School of Public Health, NY USA; [3]CSIRO Australian Animal Health Laboratory, Geelong, VIC, AUS; [4]Uniformed Services University, MD USA; [5]Duke-NUS, Singapore

Objectives: Fruit bats of the genus *Pteropus* are reservoirs for henipaviruses throughout their range. *Pteropus medius* is the natural reservoir for Nipah virus in India and Bangladesh, and mechanisms of spillover to humans primarily involves contamination of date palm sap with excreta. Serological dynamics have provided insight into patterns of Nipah virus infection in this host, but other viruses, including Nipah-like viruses have been identified through pathogen discovery techniques. Little is known about infection patterns of other viruses within this species, or their likelihood of infecting other animals or people. **Methods**: We screened sera from a single population of *P. medius* in Bangladesh collected quarterly over six years for IgG antibodies against henipaviruses (NiV, HeV, CEDV), filoviruses (EBOV, MARV), and Menangle virus, using assays containing virus-specific solubilized glycoproteins or F proteins in a Luminex platform. **Results and Conclusions:** Here we present preliminary observations of comparative temporal patterns for multiple viral agents that suggest co-circulation in this population. We also discuss challenges in interpretation of serology

when studying viral infections in wildlife, particularly when multiple antigenically related viruses may be present.

Estimating viral richness and viral sharing in bats: integrating previously-published and newly-acquired field data

Kevin J. Olival[1], Noam Ross[1], Evan A. Eskew[1], Anna R. Willoughby[1], Carlos Zambrana-Torrelio[1], Peter Daszak[1], and PREDICT Consortium[2]

[1]EcoHealth Alliance, New York, NY 10001, USA; [2]http://www.vetmed.ucdavis.edu/ohi/predict/publications/Authorship.cfm

Objectives: A handful of studies published over the last 8 years have sought to identify the host, ecological, and evolutionary factors that best explain species-level differences in viral richness in bats. Similarly, a few studies have also aimed to answer the golden question: Do bats carry a significantly larger number of total viruses, or a larger number or proportion of zoonotic viruses than other mammals? Our objective is to address these critical questions using statistical models and large datasets collated from the literature and acquired from the field. **Methods:** We collated data from the past 75 years of published for over 2800 mammal-virus associations, representing 754 mammal species and 586 ICTV-named viral species. We fit a series of generalized additive models to these data to identify and examine the functional form of significant predictor variables for total and zoonotic viral richness. Using our best-fit models we also estimate expected viral richness for each host species under a scenario of 'maximum' research effort. We map these viruses in geographic space. We also use species accumulation curves to estimate viral richness from standardized, field-acquired data from the USAID PREDICT project (http://www.healthmap.org/predict/). Network models and statistics were used to compare patterns of viral sharing among bats between the literature and field-acquired datasets. **Results:** For the all mammal analyses: The best-fit model for total viral richness per wild mammal species explained 49.2% of the total deviance, and included a per-species measure of disease-related research effort, phylogenetically corrected body mass, geographic range, mammal sympatry, and taxonomy (order) After controlling for research effort, the proportion of zoonotic viruses per species is predicted by phylogenetic relatedness to humans, host taxonomy and human population within a species range—which may reflect human–wildlife contact. We demonstrate that bats harbor a significantly higher proportion of zoonotic viruses than all other mammalian orders. For the bat field-acquired data we show significant differences in viral richness estimates across bat genera and viral family, as well as differences in the rates of saturation. Clustering in bat host-virus networks follow some predictable patterns and identify additional bat species to target for viruses of interest. **Conclusions:** These host-specific analyses and estimates of viral richness, including the unobserved or 'missing' viruses, allow us to better identify and target which species and regions should be preferentially targeted to characterize the global bat virome.

Optimised sampling efforts and screening assays identify several MERS-related coronaviruses in South African bats

Wolfgang Preiser[1,2], Ndapewa L. Ithete[1], Nadine Cronjé[1], Tasnim Suliman[1]

[1] Division of Medical Virology, Faculty of Medicine & Health Sciences, University of Stellenbosch, South Africa; [2] National Health Laboratory Service (NHLS) Tygerberg, Cape Town, South Africa

Objectives: Bats are considered reservoir hosts for all mammalian alpha- and beta-coronaviruses (α-, β-CoV). Following the emergence of SARS in 2002/03 and the subsequent identification of *Rhinolophus sinicus* as the likely ancestral SARS-CoV source, a wide diversity of bat CoV has been described worldwide. We work in transdisciplinary collaborations with ecologists and zoologists to define CoV diversity and ecology in South African bats. In addition to general "opportunistic" surveillance, species-specific studies of *Neoromicia capensis* and *Rhinolophus spp* are conducted, including longitudinal studies of bat colonies to determine shedding patterns and diversity of viruses present. **Methods:** Since 2011, 24 different bat species have been sampled along rainfall and altitudinal gradients across different biomes; namely Fynbos, Forest, Nama Karoo, Grassland, and Savanna. Sample types include faecal pellets, saliva and urine swabs, and when voucher specimens are sacrificed for museum collections, also blood and organs. Sequences of the 816bp RGU fragment (Drexler et al., 2010) for species classification were used to construct ML trees in MEGA v7. **Results:** An improved screening method greatly increased the CoV detection rate. Of 686 samples tested, 92 from 9 bat species were screening-positive: 66 for α-CoV, 19 for β-CoV, and 7 for both. The majority of sequences identified are α-CoVs, with ~20% prevalence for *N. capensis*. Preliminary analyses of partial RdRp, nucleocapsid and spike gene fragments of novel β-CoV identified in Neoromicia and Pipistrellus bats are closely related to BtCoV PML-PHE1/RSA/2011 (NeoCoV), previously found by us in a *N. capensis* and belonging to the same viral species as the recently emerged MERS-CoV, responsible for the ongoing

outbreak in the Arabian Peninsula. **Conclusions:** Extensive, dedicated sampling efforts allowed detection of α- and β-CoV from a wide range of bat species across large parts and different biomes of South Africa. An improved screening PCR approach yielded significantly more positive samples. There is substantial CoV diversity in southern African bats, including, most importantly, additional MERS-CoV-related CoV, which will hopefully help to address the unresolved question of the origin of this zoonotic pathogen.

Coronavirus diversity in bats from urban, rural and forest areas of Atlantic and Amazon Forest biomes, Brazil.

Luiz Gustavo Góes[1]; Angélica Cristine Campos[1]; Cristiano Carvalho[2]; Guilherme Ambar[5]; Douglas Oliveira[1]; Caroline Alvarenga[1]; Jhiovana Cristielly Costa[1]; Adriana Ruckert[3]; Débora C. Oliveira[3]; Luzia F. Martorelli[3]; Ana Paula Kataoka[3]; Marcelo S. Nardi[4]; Juliana L. Summa[4]; Roberta Marcatti de Azevedo[4]; Luzia H. Queiroz[2]; Ariovaldo P. Cruz-Neto[5] and Edison Durigon[1]

[1] Departamento de Microbiologia, Instituto de Ciências Biomédicas (ICB), Universidade de São Paulo (USP), São Paulo-SP; [2] Faculdade de Medicina Veterinária de Araçatuba, Universidade Estadual Paulista (UNESP), Araçatuba- SP; [3] Centro de Controle de Zoonozes (CCZ) do Município de São Paulo-SP; [4] Divisão Técnica de Medicina Veterinária e Manejo da Fauna Silvestre (DEPAVE-3), Secretaria do Verde e Meio Ambiente, Prefeitura do Município de São Paulo, São Paulo-SP; [5] Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista (UNESP), Rio Claro-SP

Objectives: Epidemiological and phylogenetic studies indicate that four out of six coronavirus capable of infecting humans are the result of spill over events of virus from bats to humans. Despite the great diversity of coronaviruses in bats, the large number of bat species in Brazil (15% of the world's bat diversity) and the presence regions classified as hotspot for zoonotic pathogen emergence only few studies have analyzed the circulation of coronaviruses in Brazilian's bats. This study aims to evaluate the diversity of CoV circulating in bats in Brazil, covering different species, habitats, and life history of the hosts. **Methods:** We analyzed 840 bats from 53 species and five bat families with a pancoronavirus detection assay. Intestine, lungs, serum and rectal/oral swabs were obtained from bats from forest, urban, and rural areas located in the Atlantic and Amazon Forest biomes. **Results:** Distinct coronavirus lineages were detected in in bats from all sites screened. The coronavirus RNA was detected in 27 individuals from eleven bat species including *Artibeus lituratus(4), Carollia perspicillata (5), Eumops glaucinus(1), Glossophaga soricina (3), Mimon crenulatum(1), Molossus rufus(2), Molossus molossus (1), Myotis nigricans(1), Myotis riparus (1), Phyllostomus discolor(1)* and *Sturnira lilium (7)*. The analysis of coronavirus phylogenetic relation from nucleotide sequences obtained showed the circulation of the 25 Alphacoronavirus genotypes (α-CoV) and two Betacoronavírus (β-CoV), distributed in thirteen lineages (eleven α-CoV and two β-CoV). Results indicate the presence of a great coronavirus diversity in bats from Brazil including potential new and already described lineages. We describe the detection of a bat coronavirus genetically related with Alphacoronavirus-1 species, which are a group of closely related viruses with an evolutionary history of recombination and cross-species transmission between domestic and livestock animals. We also report the circulation of Betacoronavirus lineage "C", related to emergent highly pathogenic coronavirus CoV-MERS, in South American bats commonly found in urban areas, representing the first detection of coronavirus Clade C in this subcontinent. **Conclusions:** Our report points to the great diversity of CoV genotypes in New World bats, more specifically in the Atlantic Forest Biome, providing a better understanding of CoV diversity, host range and biogeographic distribution.

Preliminary Evidence of a Novel Alphacoronavirus and Secondary Acquisition of Tymoviridae and Partitiviridae in Little Brown Bats (*Myotis lucifugus*) in Southcentral Alaska.

Douglas Causey[1], Jonathan C. Rupp*[1], Maegan Lange[1], Megan Howard[2], Anitha Sundarajan[3], Jonny Sena[3], Faye D. Schilkey[3], Molly Murphy[4], Sarah Cooperman[1], Eric Bortz[1]

[1]Dept. of Biological Sciences, University of Alaska Anchorage; [2]Battelle Memorial Institute; [3]National Center for Genome Resources, Santa Fe NM; [4]Dept. of Veterinary Medicine, University of Alaska Fairbanks
*Presenter

Objective: We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus*, the little brown bat. Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. **Methods**: Total RNA extracts were screened by RT-PCR and CoV ORF1a, and primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. **Results**: Sanger sequencing of amplicons confirmed the presence of an alpha-coronavirus phylogenetically related to

persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. Aligning to a reference *M. lucifigus* virus from Colorado, bat alphacoronavirus CDPHE15/USA/2006, we assembled a full-length genome (28,515nt) identifying the novel alphacoronavirus/bat/Alaska/s7/2014. A high degree of thermodynamically stable stem-loop RNA structures are predicted by Mfold within 700nt of 5' and 3' termini of genome**.** While nucleotide conservation to the Colorado virus was 96%, notable amino acid differences were identified in coronavirus proteins. In two distinct bat samples, preliminary results indicate the likely presence of tymovirus (eg. Dulcama mottle virus) probably acquired through ingestion of insects feeding on infected plants. In addition, initial results indicate presence of alpha-partitivirus closely aligned to *Rosellina*-type associated with spruce/alder and other partitivirus-like sequences. Secondary acquisition of virus obtained by feeding or incidental infection by fungi (eg. gamma-partitivirus associated with *P. destructans*) has been previously described for bats collected from similar ecological settings (eg. Thapa et al. 2016). **Conclusions**: We continue to further refine these initial for better resolution of the virome of Alaska bats.

Are big brown bat cells different than human cells in their innate immune response to coronavirus and viral ligands?

Arinjay Banerjee[1], Robert Brownlie[3], Noreen Rapin[1], Trent Bollinger[2], Darryl Falzarano[1,3] and Vikram Misra[1]

[1]Department of Microbiology, Western College of Veterinary Medicine, University of Saskatchewan, Canada. [2]Department of Pathology, Western College of Veterinary Medicine, University of Saskatchewan, Canada. [3]VIDO-InterVac, University of Saskatchewan, Canada.

Objectives: Bats are hosts for viruses such as those that closely resemble coronaviruses (CoV) that cause severe acute respiratory syndrome (SARS), Middle East respiratory syndrome (MERS) and porcine epidemic diarrhoea (PED). Despite the serious nature of these diseases in other mammalian hosts, bats naturally infected with CoV or experimentally infected with MERS-CoV do not demonstrate clinical signs of disease. We challenged big brown bat (*Eptesicus fuscus*) cells and human cells with MERS-CoV or viral ligands to study the differences in their interferon and inflammatory responses. **Methods:** *E. fuscus* kidney cell line and bone marrow derived cells, human fibroblast and epithelial cells were challenged with either MERS-CoV or poly(I:C), a double stranded RNA surrogate. Transcripts for several innate immune response genes were quantified using qRT-PCR. Interaction between the bat TNF promoter and a potential repressor of the promoter, c-Rel, was detected by chromatin co-immunoprecipitation and bat c-Rel, TLR3, RIGI and MDA5 transcripts were knocked-down using specific siRNA. **Results:** Both human and bat cells, when stimulated with poly(I:C), contained higher levels of transcripts for interferon beta than unstimulated cells. In contrast, only human cells expressed robust amount of RNA for TNFα, a cell signaling protein involved in systemic inflammation. We further observed that poly(I:C) signaled primarily through TLR3 in big brown bat cells. We examined the bat TNFα promoter and found a potential repressor (c-Rel) binding motif. We demonstrated that c-Rel binds to the putative c-Rel motif in the promoter and knocking down c-Rel transcripts significantly increased basal levels of TNFα transcripts. Both human and bat cells support replication of MERS-CoV to comparable levels. **Conclusions:** We have identified a novel transcription repressor, c-Rel, that inhibits an increase in TNFα transcripts in bat cells after poly(I:C) stimulation. We have also showed for the first time that poly(I:C) signals through TLR3 in bat cells. We are currently studying the modulation of the innate immune response in bat cells by MERS-CoV and individual MERS-CoV and bat coronavirus proteins. Identifying adaptations in the bat innate immune response might allow us to extrapolate the knowledge in identifying potential drug targets in spill-over species, such as humans.

Reverse genetic analysis of bat influenza viruses: A journey full of surprises.

Martin Schwemmle, Institute of Virology, University of Freiburg Medical Center

Our understanding of conventional influenza A viruses was recently challenged by the identification of two novel genome sequences of influenza A-like viruses from bat specimens by next-generation sequencing. Serological surveys indicate that these viruses circulate in various bat species in Central and South America. However, no viable viruses could be isolated from bats, impeding further characterization of these viruses. Interestingly, analysis of the viral surface proteins revealed that the entry machinery of these viruses differ significantly from all known conventional influenza A viruses and may only support entry into bat cells. This talk will summarize recent progress obtained by reverse genetic analysis of bat influenza A-like viruses, including the observation that the host tropisms of these viruses might be larger than anticipated.

Towards understanding bat influenza A-like viruses

Wenjun Ma[1], Bin Zhou[2], Jingjiao Ma[1], Qingfang Liu[1], Jinhwa Lee[1], Michael Duff[1], Juergen A. Richt[1], David E. Wentworth[2]

[1]Department of Diagnostic Medicine/Pathobiology, College of Veterinary Medicine, Kansas State University, Manhattan, Kansas, United States of America.

[2]Virology, J. Craig Venter Institute, Rockville, Maryland, United States of America.

Objectives: Bats harbor many viruses, which are periodically transmitted to humans resulting in outbreaks of disease (e.g., Ebola, SARS-CoV). Recently, bat influenza A-like virus HL17NL10 and HL18NL11 sequences were identified; however, no viruses were isolated from bats. This discovery aroused great interest in understanding the evolutionary history and pandemic potential of bat-influenza virus. **Methods**: Using synthetic genomics, we rescued a modified bat-influenza virus that had the HA and NA coding regions replaced with those of A/PR/8/1934 (H1N1). **Results**: This modified bat-influenza virus replicated efficiently in vitro and in mice, resulting in severe disease. The results indicate that internal genes of bat influenza A-like viruses are functional to support virial genome transcription and virus replication. Mini-genome replication studies and virus reassortment experiments demonstrated that bat influenza A-like virus has very limited genetic and protein compatibility with Type A or Type B influenza viruses, yet it readily reassorts with another divergent bat influenza A-like virus. **Conclusions**: In conclusion, our data indicate that the bat influenza A-like viruses recently identified are authentic viruses that pose little, if any, pandemic threat to humans; however, they provide new insights into the evolution and basic biology of influenza viruses.

Experimental Infection of Jamaican Fruit Bats (*Artibeus jamaicensis*) with a Rescued Bat HL18NL11 Influenza A-like Virus

Tony Schountz[1], Ashley Malmlov[1], Jingjiao Ma[2], Jinhwa Lee[2], Corey Campbell[1], Tawfik Aboellail[1], Ann Hawkinson[3] and Wenjun Ma[2]

[1]Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University; [2]Department of Diagnostic Medicine and Pathobiology, College of Veterinary Medicine, Kansas State University; [3]School of Biological Sciences, University of Northern Colorado

Objectives: Nucleotide sequences of two novel influenza A-like viruses, HL17NL10 and HL18NL11, were recently discovered in New World little yellow shouldered fruit bats (*Sturnira lilium*) and flat-faced fruit bats (*Artibeus planirostris*), respectively. Serological studies indicated high prevalence to these viruses among many species of Phyllostomidae leaf-nosed fruit bats of Central and South America, including Jamaican fruit bats (*Artibeus jamaicensis*). **Methods**: Infectious viruses have not been isolated from bats, therefore an infectious clone of HL18NL11 was generated by reverse genetics technologies that produced particles resembling influenza viruses from transfected cells by electron microscopy. Susceptibility of Jamaican fruit bats to rescued HL18NL11 bat influenza A-like virus was determined during a 28-day challenge experiment via intranasal inoculation. **Results**: The bats exhibited no overt clinical signs of disease nor fever. However, rectal swabs had up to 10^4 $TCID_{50}$ equivalents of HL18NL11 vRNA by real-time PCR in each bat on days 2, 4 and 7 post inoculation, but not day 15 or 28, and in the lungs of one of the bats on day 28 when they were euthanized. Serology showed moderate antibody titers to nucleoprotein by ELISA. Histopathology revealed mild pathology, particularly in the one bat with detectable vRNA in its lung. This bat's lungs showed multifocal mild-to-moderate histiocytic and lymphoplamacytic interstitial pneumonia. Pleocellular infiltrates were especially prominent around adventitia of pulmonary arterioles. Immunohistochemistry with mouse antibody to recombinant H18N11 nucleoprotein revealed virus antigen in the lungs of this bat. **Conclusions**: This is the first study to demonstrate susceptibility to bat influenza viruses and suggests that viral persistence up to 28 days may occur in some bats, supporting the hypothesis that Jamaican fruit bats may be a natural reservoir host of the HL18NL11 virus.

Seroprevalence of alphaviruses, flaviviruses and Rift Valley fever virus in Ugandan bats

Kading RC[1,2], Kityo R[3], Mossel E[1], Borland E[1], Nakayiki T[4], Nalikka B[3], Nyakarahuka L[4], Ledermann J[1], Panella N[1], Gilbert A[5,6], Crabtree M[1], Kerbis Peterhans J[7], Towner J[8], Amman B[8], Sealy T[8], Nichol S[8], Powers A[1], Lutwama J[4], Miller B[1]

[1]Centers for Disease Control and Prevention, Division of Vector-borne Diseases, Arbovirus Diseases Branch, Fort Collins, CO; [2]Current Affiliation: Colorado State University, Department of Microbiology, Immunology and Pathology, Fort Collins, CO; [3]Makerere University, Department of Biological Sciences, Kampala, Uganda; [4]Uganda Virus Research Institute, Entebbe, Uganda; [5]Centers for Disease Control and Prevention, Division of High Consequence Pathogens, Rabies and Poxvirus Branch, Atlanta, GA; [6]Current Affiliation: United States Department of Agriculture, Animal and Plant Health Inspection Service, Fort Collins, CO; [7]College of Professional Studies, Roosevelt University &Collections & Research, The Field Museum of Natural History, Chicago, IL;

[8]Centers for Disease Control and Prevention, Division of High Consequence Pathogens, Viral Special Pathogens Branch

Objectives: Arboviruses including Rift Valley fever virus (RVFV), chikungunya virus (CHIKV) and Sindbis viruses have previously been isolated from naturally-infected East African bats, however the role of bats in arbovirus transmission cycles is poorly understood. The aim of this study was to investigate the exposure history of Ugandan bats to a panel of arboviruses. **Methods**: Insectivorous and fruit bats were captured from multiple locations throughout Uganda between 2009 – 2013. All bat captures were conducted under the approval of IACUC protocols 1731AMMULX (Maramagambo samples) and 010-015 (all other samples). Bats were captured using harp traps or mist nets, taking appropriate biosafety precautions. All serum samples were frozen at -80°C until they were tested for neutralizing antibodies against West Nile virus (WNV), yellow fever virus (YFV), Dengue 2 virus (DENV-2), Zika virus (ZIKAV), CHIKV, o'nyong-nyong virus (ONNV), Babanki virus (BABV), and RVFV by plaque reduction neutralization test (PRNT). **Results**: Sera from up to 626 bats were screened for neutralizing antibodies against each virus. Key findings include the presence of antibodies against ONNV in approximately 15% (44/303) of Egyptian rousette bats (*Rousettus aegyptiacus*) from Maramagambo forest in western Uganda, and antibodies against RVFV in Ethiopian epauletted fruit bats (*Epomophorus labiatus*) captured from Kawuku (5/52) and Egyptian rousette bats from Kasokero cave (3/54). **Conclusions**: Antibodies reactive to flaviviruses were widespread across bat taxa and sampling locations.The data presented demonstrate the widespread exposure of bats in Uganda to arboviruses, and highlight particular virus-bat associations that warrant further investigation.

Presence of zoonotic bat pathogens correlate with reproductive seasons in South African bat populations
Wanda Markotter[1], Muriel Dietrich[1], Teresa Kearney[2,3], Stewart McCulloch[1], Marinda Mortlock[1], Ernest Seamark[4,5] and Janusz Paweska[6]

[1] Centre for Viral Zoonoses, Department of Medical Virology, Faculty of Health Sciences, University of Pretoria, South Africa; [2] Ditsong National Museum of Natural History, Pretoria, South Africa.; [3] Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa; [4] AfricanBats, Kloofsig, South Africa. [5] Centre for Wildlife Management, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, South Africa; [6] Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, South Africa.

In 2003 we initiated passive surveillance on bats in South Africa with the initial objective to identify rabies–related lyssaviruses, but this has since expanded to include several other possible zoonotic viral and bacterial pathogens. The project has identified viruses in the following families; *Rhabdo, Paramyxo, Bunya, Filo*, *Adeno-, Herpes-, Picorna, Orthomyxo, Circo, Parvo, Papilloma* and *Coronaviridae* as well as the following bacterial pathogens; *Leptospira*, *Rickettsia and Bartonella.* **Objectives:** To determine longitudinal circulation of pathogens we initiated seasonal sampling from 2012 in two cave systems in South Africa. This sampling specifically focused on the reproductive seasons of *Rousettus aegyptiacus* and *Miniopterus natalensis*. **Methods:** Serum was analysed for rabies related lyssavirus, Lagos bat virus, antibodies using a virus neutralization assays. Tissue, urine saliva and fecal samples were tested for the presence of viral nucleic acids using RT-PCR/PCR specific for several viral families. Illumina MiSeq 16S rRNA gene sequencing on low-biomass individual bat samples was used to identify bacterial pathogens. **Results:** Longitudinal studies, specifically focused on measuring the presence of LBV antibodies in *Rousettus aegyptiacus*, indicated cyclic fluctuation of antibodies with a marked increase shortly after the parturition period, which identified this as a high risk period for spill-over. We showed that seasonal bat reproduction is a major driver shaping temporal variations in microbial community structure. A strong temporal shift in oral, fecal and urinary microbiota was also associated with bat reproduction, with significant associations between the microbiota and the sex, or reproductive status. **Conclusion**: This cumulative evidence can be used to indicate periods of increased viral and bacterial circulation, which can be used to make public and veterinary health decisions on spill-over risks.

Body mass index of the Egyptian fruit bat, *Rousettus aegyptiacus*: An indicator of infection status
Low J. de Vries, [1], Stewart McCulloch[1], Janusz Paweska[2] and Wanda Markotter[1]

[1] Centre for Viral Zoonoses, Department of Medical Virology, Faculty for Health Science, University of Pretoria, South Africa; [2] Center for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, Johannesburg, South Africa

Body mass in conjunction with forearm length has long been used to determine body mass indices for bats. These indices have been further linked to diseases detected in bats, with a low body mass index being a potential indicator of infected bats. **Objectives**: We correlated body measurements to body mass, enabling us to determine

the best measurement that could be used to build body mass indices which can be correlated to disease status of *Rousettus aegyptiacus.* **Methods**: This study focuses on the Egyptian fruit bat (*Rousettus aegyptiacus*) in the Limpopo Province of South Africa. Data was gathered over a two year period, 2015 and 2016, and consisted of measurements of various body parts. **Results**: Wilcoxon Matched pair tests indicated a significant difference in body weight between the two sampling years (V = 34476, p = 0.002466). A strong correlation was found between body mass and forearm length when both years are considered (S = 17252000, p-value < 2.2e-16), as well as for the first (S = 3487900, p-value < 2.2e-16) and second year (S = 1250500, p-value < 2.2e-16) of the study with a strong correlation value; R > 0.78 in all cases. The correlation between mass and forearm length was significant for both males and females during both years (p-value < 2.2e-16), but the correlation value was always lower for females. Other body measurements correlated significantly with body mass, but only forearm length showed a strong correlation. **Discussion**: Forearm length is thus an indicator of body mass in Egyptian fruit bats, as has been found for insectivorous bats. As such, body mass in conjunction with forearm length could be used to build body mass indices, which could be used as a preliminary indicator of disease status for *Rousettus aegyptiacus.*

Environmental constraints drive the viral diversity of two sympatric Amazonian bat species
Arielle Salmier, Sourakhata Tirera, Benoit de Thoisy, Alain Franc, Edith Darcissac, Damien Donato, Christiane Bouchier, Vincent Lacoste and Anne Lavergne

Institut Pasteur de la Guyane

Amazonia is a major biodiversity hotspot which encompasses a great diversity of bat species, as well as a wide variety of climates and vegetation formations. Landscape characteristics (*e.g*. climate, vegetation structure, anthropogenic disturbances) are relevant predictors of species richness and influence the host-pathogens relationships. However, the effects of contrasting environmental conditions on the viral diversity harbored by Amazonian bats have yet to be investigated. Through a metagenomic approach we characterized the viral diversity of two sympatric Amazonian bat species: the common vampire bat, *Desmodus rotundus* (*Phyllostomidae*) and the insectivorous bat, *Molossus molossus* (*Molossidae*). Then, through a statistical approach, we assessed the impact of the landscape characteristics by comparing the viral richness harbored by different populations of vampires and insectivorous bats inhabiting different environments (*e.g.*, forests, edge habitats, anthropized and urban areas). We identified 10,983 viral sequences related to 48 viral families known to infect a wide range of hosts (*i.e.*, bacteria, plants, insects and vertebrates). Most viruses detected reflect the dietary habits, especially within the insectivorous bat species which presented the highest diversity of plant and insect-related viral families. Diversity tests and phylogenetic relationships reconstructed for several mammal-related viral families (*e.g.*, *Bunyaviridae*, *Circoviridae*, *Foamyviridae*, *Herpesviridae*, *Papillomaviridae*) revealed a preferential transmission route within phyla of bats, as well as a potential association of viral diversity with the host's gut microbiota. Three structuring poles related to species traits and environments were identified, explaining the distribution of viral diversity and showed a strong correlation between the type of environment, host phylogeny, diet and viral diversity. The substantial viral richness detected in forest environments is likely due to a wider diversity of prey and favored by more frequent contacts between hosts and overlapping habitats. These findings provide significant insight into viral bat diversity in Amazonia and emphasize that environmental constraints and host features are the main drivers of viral diversity in bat species.

Seasonal and individual predictors of grey-headed flying fox (*Pteropus poliocephalus*) foraging movements in Adelaide, South Australia
Cecilia A. Sánchez[1,2], Terry B. Reardon[3], Wayne S.J. Boardman[4] and Sonia Altizer[1,2]

[1]Odum School of Ecology, University of Georgia, Athens, GA, USA; [2]Center for the Ecology of Infectious Diseases, University of Georgia, Athens, GA, USA; [3]South Australian Museum, Adelaide, South Australia, Australia; [4]University of Adelaide, Adelaide, South Australia, Australia

Objectives: The distribution of flying foxes in Australia is influenced by the unpredictable availability of their preferred diet, especially eucalypt blossoms. Recently, human activities, including destruction of native habitat and planting of non-native vegetation that provides predictable foraging, have altered the distribution and movements of flying foxes. The consequences of this change are important for both bat and human health, given that bats are reservoirs of Australian bat lyssavirus and Hendra virus, both of which cause fatal disease in humans. In 2010, grey-headed flying foxes (*Pteropus poliocephalus)* established a permanent roost in Adelaide, South Australia, several hundred kilometers outside their previous range. Despite incurring juvenile mortality due to extreme heat events, the population now numbers approximately 7000 and is expected to continue growing. **Methods:** As part of a larger study to characterize the health and behavior of the Adelaide flying fox population, we deployed lightweight GPS loggers on bats to track their foraging movements. Loggers recorded a bat's position every 30 seconds when flying and every 45 minutes when stationary, and also recorded acceleration,

speed, and altitude data. Forty foraging sites were ground-truthed to identify feeding resources. **Results:** Five flying foxes were tracked in winter 2016 and 9 in summer 2017, resulting in 112 nights of movement data. Bats exhibited individual variation in movement patterns, with some foraging repetitively, and others ranging more widely over the landscape. The nightly distance traveled depended on the interaction between sex and the ratio of weight to forearm length, but not on season. In the summer, bats foraged predominantly on urban resources, with figs and eucalypts being especially popular. **Conclusions:** This work provides insight into a recently-established, understudied bat population and is useful both to local Adelaide stakeholders as well as other urban citizens seeking to manage the bats that share their space. Foraging on urban resources, especially in residential yards, could increase the chances for disease transmission from flying foxes to humans and pets. Individual predictors of movement should be considered when building models of bat movement and disease risk.

Uganda Bat calls library-developing a tool to survey arthropod-borne viruses associated with Chiroptera
Kityo Robert Martin[1], Kading Rebekah[2], Nalikka Betty[1], Lutwama Julius[3]
[1]Makerere University, College of Natural Science – Department of Zoology, Entomology and Fisheries Science Kampala Uganda; [2]Colorado State University; [3]Uganda Virus research institute

Objectives: We continue to conduct studies of bats in different parts and habitats of Uganda with a number of particular goals: -

i. To continue to understand the occurrence and ecology of bats that may be reservoirs and/or vectors of viruses in Uganda (BM presentation),
ii. To develop a micro-chiroptera calls Library for the country
iii. Continue the development a fast approach that can be used to quickly survey and identify the bat fauna of different parts of Uganda.
iv. To investigate the roles of different species of bats in the ecology of viruses (RK presentation),

Methods: Through a DTRA supported project we particularly targeted to understand bat ecology and their potential roles in virus ecology. This was done through graduate training and research, training in field techniques of capture and processing of bats for detection of and characterization of viruses a pillar institutional players and a compilation of reference calls of micro-chiropteran bats for Uganda. Field biosurveillance training was held with participants from NADDEC, UVRI and Makerere University at Zika forest. A graduate student now preparing his dissertation, was recruited and completed an ecological study on bats in the Kaptum cave. Insect bats are captured using Mist nets, Herp traps and Hand net capture at roost sites. Bats are either free flown, ziplined or light tagged and hand released from which voucher calls are collected. Collected calls are processed using Kaleidoscope Pro version 31.7 for large files that need to be split for examination and processing in Sonobat4.0.6p. **Results**: Cumulatively, voucher calls for 50 species of micro chiropteran bats (over 50% of the Ugandan species) have been collected. Several of these are represented by multiple bats that way taking care of potential intra specific variations, potential ecological variations each of which could affect the call produced by the species. This presentation specifically shares our findings on call characteristics for a sample of the species and highlights the great overlap in signatures for species of Molosid bats, species of the Genus *Scotophilus*, while showing very nicely segregated call signals for Hipposiderid, Rhinolophid and a good number of verspertilionid bats. **Conclusions**: Our next steps are to attempt to collect voucher calls from species we haven't, collect additional calls from species already recorded but from few individuals, and to work with partners to develop a tool that could be used to rapidly identify calls collected from bat detection surveys from different parts of the country.

Dampening of STING-dependent IFN production: an implication of virus tolerance in bats?
Jiazhen Xie[1], Chenxi Ma [1], Yang Li[1], Jie Cui[1], Linfa Wang [2], Zhengli Shi [1] and Peng Zhou[1*]

[1]Wuhan Institute of Virology, Chinese Academy of Sciences, Wuhan 430071, China; [2]Emerging Infectious programme, Singapore Duke-NUD Medical School, Singapore 169857, Singapore

Objectives: Bats are known to harbour a number of zoonotic viruses, many of which are highly pathogenic in human but result in no clinical symptoms in bats. The mechanism of how bats coexist with viruses is still largely unknown. We previously reported the contraction of type I IFN locus and unusual constitutively expression of IFNA in bats. We hypothesis this may help bat to inhibit virus replication. However, as immune response can also do harm to the host, then how bats tolerate viruses and viral induced immune responses become a question. **Methods:** To address this question, we scanned a list of DNA and RNA sensors in bats. We then focus on STING, which played a key role in multiple DNA sensing pathways, for understanding how bats tolerate DNA viruses. We also tested the functionality of bat STING in a list bat immune or non-immune cells. **Results and Conclusions:** We found some of the viral DNA sensors are under faster evolution, implying a change of function. Further experimental data also confirmed the dampening of viral DNA sensing, more specifically STING- dependent IFN production pathway. We then identified a ubiquitous key point mutation in all bat species tested, which hugely

decreased the cGAS-STING sensing ability (80%) by gain-of-function studies. Lastly, we restored the functionality of STING and STING-dependent viral DNA sensing pathway by changing this site to human. We conclude that bat naturally own a dampened STING-dependent IFN production, probably to avoid over responses to virus. This observation provides a model of how bats tolerance thus long-term hosting these viruses.

Regulation of immune activation and dampened inflammation in Pteropid bats
Aaron T. Irving[1], Katarina Luko[1], Matae Ahn[1], Kong Pui San[1], & Lin-Fa Wang[1]

[1]Duke-NUS Medical School, Singapore

Objective: Natural reservoir hosts can maintain low-level infection of pathogens without succumbing to severe disease. Several bat species host viruses such as Ebola, SARS, Nipah, Hendra, and other pathogenic viruses and while these same infections cause mass-inflammation in humans and other animals they are mostly asymptomatic in the bat. As such, bats are a unique model for studying the host control of systemic inflammation. **Methods:** We utilised bat cell lines, primary cells and tissue with qPCR, Western Blot, FACS analysis, NGS transcriptomics and cellular proteomics to profile pathways and characterise signalling mechanisms. **Results:** Through studying immune activation to flaviviruses, influenza and reovirus, along with natural stimulants of innate immunity such as TLR and RLR ligands we are beginning to characterize key differences to their human counterparts for PRRs.. There appears to be differences also in the kinetics and activation signals required for Interferon activation also. In addition, our data, from investigation of primary bat immune cells and studying bat homologs, suggests that inflammasome activation pathways may be altered with dampened activation of downstream inflammation. **Conclusion:** Along with fundamental differences to cell biology, this may indicate an evolutionary adaptation that while supporting flight, may cause susceptibility to infection yet maintain a symbiotic state with several pathogens. Initial observations show several key mutations, altered kinetics and a decrease in sensitivity to induce signaling all appear to be involved. From this we can gain understanding into a mechanism for controlling excess inflammation in humans.

Delineating the phenotype and function of the B cell population in the fruit-eating bat, Pteropus Alecto.
Periasamy P.[1,2], Martínez Gómez J.M.[1,2], Wang LF[3] , and Alonso S.[1,2]
[1]Department of Microbiology and Immunology, [2]Immunology Programme, Yong Loo Lin School of Medicine, Life Sciences Institute, National University of Singapore, Singapore. [3]DUKE-NUS, Singapore.

Objective: The unique ability of bats to act as reservoir for viruses that are highly pathogenic to humans suggests unique properties and functional characteristics of their immune system. However, the lack of bat specific reagents, in particular antibodies, has limited our knowledge of bat's immunity.
Methods: Here, using cross-reactive antibodies, we report the phenotypic and functional characterization of B cells based on anti-mouse I-Ab (MHC-II) and anti-bat IgG. **Results**: Using flow cytometry, we show their distribution amongst the major lymphoid organs and scanned electron micrographs of these sorted population reveal that they are morphologically similar to human and murine B cells. In addition, a large population of these cells test positive for CD19 mRNA, tested using SmartFlare RNA probes, and anti-human CD19 antibody. Uniquely, these cells are able to show an increase in calcium uptake upon cross-linking of their B cell receptor with the addition of secondary donkey anti-goat antibody, which is specific for the goat anti-bat IgG. We also demonstrate T cells and myeloid cells do not release calcium in the presence of IgG and secondary antibody. Furthermore, we also demonstrate that injecting LPS for 5 hrs show an increase in MHC-II$^+$IgG$^+$ B cell population in the spleen and blood. This demonstrates a T-independent B cell activation amongst the B cell population. In addition, this population of cells do not respond to Poly (I:C) stimulation. We also performed single cell RNA sequencing on sorted MHC-II$^+$IgG$^+$CD19$^+$ positive cells to identify various B cell subsets based on their gene signature. Initial analysis reveal that these cells show increased expression of CD19 and do not express CD3, CD8 and CD11b. **Conclusions**: Here, we demonstrate for the first time the phenotype and function of B cells in *Pteropus Alecto.* This provides us with a platform to isolate and further elucidate the role of these cells in infectious models.

Integrative measures for assessing "health" in free-ranging bats – zoonotic and conservation implications from a One Health perspective

DeeAnn M. Reeder[1], Kenneth A. Field[1]

[1]Department of Biology, Bucknell University

Objectives: Risks of zoonotic spillover are likely related to the overall health of the animal host. For bat hosts of viral zoonotic diseases, the relationship between health and spillover risk is complex, with poor health possibly favoring transmission by increasing viral load and shedding but also decreasing animal mobility and human-host contact. Unfortunately, determining the health status of free-ranging bats is fraught with difficulty. Challenges exist not only in deciding which diagnostic measures to use, but also in interpreting the results of these measures. Furthermore, without the ability to measure fitness in these long-lived mammals, our understanding of the consequences of "good" or "bad" health for a free-ranging bat is poor. Our objective is to provide a framework for defining bat health that will facilitate bat studies and will enhance our understanding of spillover risk, ecosystem health, and human health. **Methods:** We combined an extensive literature review of health metrics in free-range wildlife, including bats, with our own long-term field studies and experiences studying bat physiology and disease. **Results:** Literature review and our past work point to several findings: (1) a number of measures commonly used in other vertebrate taxa and in other mammals have not been fully deployed for bats – sometimes owing to methodological hurdles; (2) due to a lack of tools, and often small sample volumes, most bat studies have relied on too-few measures, such as BMI (which suffers from allometric problems and is often surprisingly uninformative), the ubiquitous neutrophil-to-lymphocyte (N/L) ratio, ectoparasite load, and highly variable immune metrics such as hemmaglutination assays; (3) newer molecular methods, such as transcriptomic approaches hold promise for improving our understanding of bat health, especially when integrated with other measures such as infection status. We will present preliminary data from our recent field studies of African fruit bats in which we have deployed 20+ field diagnostic measures in combination with infection status and a transcriptomic approach. **Conclusions:** We recommend the development of integrative health metric(s), which will allow for the determination of the most informative measures for future studies. We also implore researchers to document normative physiological measures for more species of bats, analyzed with regards to life history, ecology, and phylogeny.

Host-pathogen interactions during white-nose syndrome

Ken Field[a], Sophia M Reeder[a], Jonathan M Palmer[b], Brent J Sewall[c], Jenni M Prokkola[d], Greg Turner[e], Thomas M Lilley[f], Marianne Gagnon[c], J Paul White[g], Joseph Johnson[h], Christopher Hauer[c], and DeeAnn M Reeder[a]

[a]Department of Biology, Bucknell University, Lewisburg, PA; [b]Center for Forest Mycology Research, Northern Research Station, US Forest Service, Madison, WI; [c]Department of Biology, Temple University, Philadelphia, PA; [d]University of Eastern Finland, Joensuu, Finland; [e]Wildlife Diversity Division, Pennsylvania Game Commission, Harrisburg, PA; [f]Institute of Integrative Biology, University of Liverpool, Liverpool L69 3BX, UK; [g]Wisconsin Department of Natural Resources, Madison, WI ; [h]Biological Sciences, Ohio University, Athens, OH

Objectives: We have employed a dual RNA-Seq approach to study gene expression of both host and pathogen during the fungal infection that causes white-nose syndrome (WNS) in bats. **Results**: We have found that when *Pseudogymnoascus destructans* is causing WNS, the most significant differentially expressed genes in the pathogen were involved in heat shock responses, cell wall remodeling, and micronutrient acquisition. These results demonstrate that this fungal pathogen responds to host-pathogen interactions by regulating gene expression in ways that may contribute to evasion of host responses. We have also found that host responses vary between susceptible and resistant species of bats in ways that may indicate that host responses contribute more to pathogenesis than to protection. This may be because, during hibernation, host immune responses are too costly and lead to premature depletion of energy reserves. We have also determined which host transcriptomic responses to fungal infection can occur during torpor and which require arousal to euthermy. We found relatively few host transcripts that showed significant changes in expression levels due to fungal infection in torpid bats compared to euthermic bats. **Conclusions**: These results support the view that torpor is a period of relative dormancy and suggest that periodic euthermic arousals exist to provide an opportunity for host responses to pathogens.

Resistance or Tolerance – How do European bats cope with *Pseudogymnoascus destructans*?
FRITZE M[1,2], VOIGT CC[2], CZIRJAK GA[2], PUECHMAILLE SJ[1,3].

[1] Zoology Institute,University of Greifswald,Soldmann-Str. 14, D - 17487 Greifswald, Germany; [2] Leibniz institute for Zoo and Wildlife Research, Alfred-Kowalke-Str. 17, 10315 Berlin, Germany and [3] School of Biology and Environmental Sciences, University College Dublin, Belfield, D4 Dublin Ireland

Objectives: *Pseudogymnoascus destructans* (*Pd*), the causing agent of the White-nose disease, colonizes bats during hibernation. The cold-loving fungus affects the snout and all the hairless skin membranes of torpid bats where it causes lesions. The spreading epidemic in North America (so called White-nose syndrome) is characterized by mass mortalities and regional extinctions of certain bat populations. In Europe, *Pd* has been recorded since several decades as a widespread pathogen, yet it does not cause mass mortalities. Several studies confirm that *Pd* is native to Europe and appeared as a new pathogen in North America in 2006. If and how European bats adapted to the disease and why North American bats cannot cope with the fungus remains unclear. **Methods**: We analysed data from over 300 hibernacula across Europe to test for factors influencing mortality, including *Pd* infections on bats. **Results**: Our results show an overall low mortality rate of bats in Europe with no evidence of *Pd*-associated mortalities. Physiological data and blood samples from infected and non-infected European bats were analysed to investigate, if bats suffer from White-nose disease and how the immune systems reacts to fungal infections during hibernation. **Conclusions**: Our ecological, physiological and immunological results suggest resistance and tolerance of European bats towards *Pd*.

Modeling the impact of White-nose syndrome on two western bat species
C. Reed Hranac[1], Brandon J. Klüg-Baerwald[2], Yvonne A. Dzal[3], Cori Lausen[4], Jonathan C. Marshall[1,5], Sarah H. Olson[6] , David T. S. Hayman[1]

Affiliations: [1] Hopkirk Research Institute, Massey University, Private Bag, 11 222, Palmerston North 4442, New Zealand; [2] Department of Biology University of Regina, Regina, SK, Canada, 3737 Wascana Parkway, Regina, SK S4S 1T8; [3] Department of Zoology, University of British Columbia, Vancouver, BC, Canada #4200-6270 University Boulevard, Vancouver, BC V6T 1Z6, [4] Wildlife Conservation Society Canada, Kaslo, BC, Canada, P.O. Box 606, 202 B Ave, Kaslo, BC V0G 1M0; [5] Institute of Fundamental Sciences Massey University, Private Bag 11 222, Palmerston North 4442, New Zealand; [6] Wildlife Conservation Society, Wildlife Health Program 212 South Wallace Avenue, Suite 101, Bozeman, MT, 59715, USA

Objectives: The rapid westward spread of white nose-syndrome (WNS) through North America has become a critical conservation issue for endemic hibernating bat species with many Eastern populations experiencing steep declines over the last ~10 years. The continued spread of the psychrophilic fungus *Pseudogymnoascus destructans* into Western states over the last two years has the potential to impact many hibernating species. Disease outcome varies widely between species, with infection of some species (namely European and Asian species) being largely benign. The identification of species that may be threatened is paramount to development of effective conservation strategies. **Methods:** Using field obtained morphometric data in conjunction with experimentally obtained estimations of key metabolic parameters we applied a modified hibernation model that includes fungal growth dynamics for two currently unaffected North American bat species: *Myotis californicus* and *Myotis yumanensis*. **Results:** Infection of *P. destructans* would likely reduce the maximal time spent in hibernation for both Western *Myotis* species. Reductions of maximal time spent in torpor were predicted to be the most drastic in microclimates with relative humidity approaching saturation and temperatures between ~5 °C and 10 °C. Despite the increased rate of overwinter energy consumption, fat reserves were still predicted to be sufficient to overwinter throughout the majority of their distribution. **Conclusions:** *M. californicus* and *M. yumanensis* are predicted not to experience distribution wide population declines like those witnessed for *M. lucifugus* and *M. septentrionalis* in eastern North America. Continuing field studies will provide data on important model parameter estimations, more species, realized hibernacula microclimate selection, and providing data to empirically validate model predictions.

Variable behaviors influence species susceptibility to disease – surviving white-nose syndrome.
Paul M. Cryan, Research Biologist,
U.S. Geological Survey (USGS), USGS Fort Collins Science Center, 2150 Centre Ave., Bldg. C, Fort Collins, Colorado 80526;

White-nose syndrome (WNS) continues to spread through populations of hibernating bats in North America, causing unprecedented mortality in several species occurring in eastern parts of the continent. Despite this devastation, other bat species that come into contact with the causative fungus, *Pseudogymnoascus destructans*, somehow survive. We still do not understand factors influencing species and continental differences in bat

susceptibility to WNS, but variability of innate behaviors among taxa and regions may help explain disease survival. This talk focuses on evidence suggesting infected bats can exploit 'survival habitats' (e.g., hibernacula with palliative microclimates) and 'survival behaviors' (e.g., palliative ways of regulating body temperature during winter). Our search for survival habitats and behaviors in WNS bats illustrates the challenges of understanding how microorganisms influence their cryptic hosts, how unknown host behaviors can obscure understanding of disease, and how new bat research methods may help overcome some of these challenges.

Emerging Insights into the Geographic Distribution, Genetic Diversity and Evolutionary Origin of Bat-borne Hantaviruses

Satoru Arai[1], Se Hun Gu[2], Son Truong Nguyen[3], Vuong Tan Tu[3], Blaise Kadjo[4], Burton K. Lim[5], Joseph S. Masangkay[6], Saw Bawm[7], Joseph A. Cook[8], Shigeru Kyuwa[9], Keiko Tanaka-Taya[1], Shigeru Morikawa[1] and Richard Yanagihara[2]

[1]National Institute of Infectious Diseases, Tokyo, Japan; [2]University of Hawaii at Manoa, Honolulu, HI, USA; [3]Institute of Ecology and Biological Resources, Vietnam Academy of Science and Technology, Hanoi, Vietnam; [4]University of Félix Houphouët-Boigny, Abidjan, Côte d'Ivoire; [5]Royal Ontario Museum, Toronto, Canada; [6]University of the Philippines Los Baños, Laguna, Philippines; [7]University of Veterinary Science, Nay Pyi Taw, Myanmar; [8]University of New Mexico, Albuquerque, New Mexico, U.S.A.; [9]University of Tokyo, Tokyo, Japan;

Objective: The recent discovery of genetically distinct hantaviruses in multiple species of shrews and moles (order Eulipotyphla) prompted a further exploration of their geographic distribution, genetic diversity and evolutionary relationships by analyzing tissues and feces from bats (order Chiroptera). **Methods:** Total RNA, extracted from frozen, ethanol-fixed or RNAlater®-preserved archival tissues (lung, liver, kidney, intestine, intercostal muscle) and rectal swab/feces of 1,890 bats, representing 10 families (Emballonuridae, Molossidae, Mormoopidae, Nycteridae, Phyllostomidae, Vespertilionidae in the Yangochiroptera suborder, and Pteropodidae, Hipposideridae, Megadermatidae, Rhinopholidae in the Yinpterochiroptera suborder), collected in Asia (China, Korea, Malaysia, Mongolia, Myanmar, Philippines, Republic of Georgia, Vietnam), Africa (Côte d'Ivoire, Guinea, Liberia) and the Americas (Bolivia, Brazil, Guyana, USA) during 1981–2015, were analyzed for hantavirus RNA by nested RT-PCR. Phylogenetic analysis was performed using maximum likelihood and Bayesian methods. **Results**: Hantavirus RNAs were detected in 2 of 12 *Neoromicia nanus* from Côte d'Ivoire (Mouyassué virus, MOYV), 6 of 49 *Hipposideros pomona* and 1 of 5 *Hipposideros cineraceus* from Vietnam (Xuan Son virus, XSV), 1 of 12 *Aselliscus stoliczkanus* from Vietnam (Dakrong virus, DKGV), 2 of 13 *Taphozous melanopogon* from Myanmar (Laibin virus, LBV), and 1 of 15 *Rousettus amplexicaudatus* from the Philippines (Quezon virus, QZN). Multiple attempts to acquire whole genomes of the newfound hantaviruses were unsuccessful, except for DKGV and QZNV. Phylogenetic analyses indicated incongruent topologies for each genomic segment, presumably because of the limited sequences available for most of the hantaviruses harbored by bats, shrews and moles. However, in both the S- and L-segment trees, QZNV appeared to share a common ancestry with XSV and LBV. Based on the host cytochrome *b* sequences, the phylogenetic positions of bats in the Yinpterochiroptera and Yangochiroptera suborders were consistent with the phylogenetic relationships among the bat-borne hantaviruses. **Conclusions:** Other research teams have reported Magboi virus in *Nycteris hispida* from Sierra Leone, Makokou virus in *Hipposideros ruber* from Gabon, Huangpi virus in *Pipistrellus abramus* from China, Longquan virus in *Rhinolophus affinis, Rhinolophus monoceros* and *Rhinolophus sinica* from China, Laibin virus in *Taphozous melanopogon* from China, and Brno virus in *Nyctalus noctula* from the Czech Republic, bringing to 11 the number of bat-borne hantaviruses to date. As in shrews, moles and rodents, the same hantavirus species was occasionally found in more than one bat species, and the same bat host species occasionally harbored more than one hantavirus species, suggesting that the formerly held conventional view of one hantavirus species and one host species is no longer tenable. Moreover, the basal position of the chiropteran-borne hantaviruses in phylogenetic trees and the demonstration that bat species in both suborders harbor hantaviruses suggest that primordial hantaviruses may have emerged in an early common ancestor of bats or other members of the Laurasiatheria superorder, that includes shrews and moles.

Neotropical Bats that Co-habit with Humans Function as Dead-End Hosts for Dengue Virus

Amanda Vicente-Santos[1,2], Andres Moreira-Soto[1,4], Claudio Soto-Garita[1], Luis Guillermo Chaverri[3], Andrea Chaves[2], Jan Felix Drexler[4,5], Juan Alberto Morales[6], Alejandro Alfaro-Alarcón[6], Bernal Rodríguez-Herrera [2] and Eugenia Corrales-Aguilar [1*]

[1]Virology-CIET (Research Center for Tropical Diseases), Microbiology, University of Costa Rica, San José, Costa Rica. [2]Biology, University of Costa Rica, San José, Costa Rica. [3]Exact and Natural Sciences School, National Distance Education University, San José, Costa Rica. [4]Institute of Virology, University of Bonn Medical Centre, 53127 Bonn, Germany.[5]German Centre for Infection Research, Bonn-Cologne, Germany.[6] Department of Pathology, School of Veterinary Medicine, National University, Costa Rica

Objective: Several studies have shown Dengue Virus (DENV) nucleic acids and/or antibodies present in Neotropical wildlife including bats, suggesting that some bat species may be susceptible to DENV infection. Here we aim to elucidate the role of house-roosting bats in the DENV transmission cycle. **Methods**: Bats were sampled in households located in high and low dengue incidence regions during rainy and dry seasons in Costa Rica. We captured 318 bats from 12 different species in 29 households. Necropsies were performed in 205 bats to analyze virus presence in heart, lung, spleen, liver, intestine, kidney, and brain tissue. **Results**: Histopathology studies from all organs showed no significant findings of disease or infection. Sera were analyzed by $PRNT_{90}$ for a seroprevalence of 21.2% (51/241), and by PCR for 8.8% (28/318) positive bats for DENV RNA. From these 28 bats, 11 intestine samples were analyzed by RT-PCR. Two intestines were DENV RNA positive for the same dengue serotype detected in blood. Viral isolation from all positive organs or blood was unsuccessful. Additionally, viral load analyses in positive blood samples by qRT-PCR showed virus concentrations under the minimal dose required for mosquito infection. Simultaneously, 651 mosquitoes were collected using EVS-CO_2 traps and analyzed for DENV and feeding preferences (bat cytochrome b). Only three mosquitoes were found DENV positive and none was positive for bat cytochrome b. Our results suggest an accidental presence of DENV in bats probably caused from oral ingestion of infected mosquitoes. Phylogenetic analyses suggest also a spillover event from humans to bats. **Conclusion**: Therefore, we conclude that bats in these urban environments do not sustain DENV amplification, they do not have a role as reservoirs, but function as epidemiological dead end hosts for this virus.

Novel Gammaherpesvirus in Bats: discerning the secrets of these oncogenic viruses

Sonu Subudhi[1], Noreen Rapin[1], Janet Hill[1] and Vikram Misra[1]

[1]Department of Veterinary Microbiology, University of Saskatchewan, Saskatoon, Canada

Objectives: *Gammaherpesvirinae* is a subfamily of herpesviruses which often cause lymphoproliferative diseases and have been linked to two human lymphoid cancers – Burkitt's lymphoma and Kaposi's sarcoma. Anecdotal evidence suggests that bats have lower rates of cancer than other mammalian species. This phenomenon may be because bats have evolved efficient mechanisms for detecting and repairing damaged DNA as a by-product of flight. How such a mechanism affects the interaction of Gammaherpesviruses (which cause cancer) with their bat, hosts is largely unknown. **Methods and Results:** We have isolated a novel Gammaherpesvirus (*Eptesicus fuscus* herpesvirus – EfHV) from a North-American Big Brown bat (*Eptesicus fuscus*). We have used a big brown bat cell line to study the growth kinetics of the virus. We have also performed electron microscopy and PCR to confirm that the virus belongs to the herpesvirus family. To determine the sequence of the herpesvirus, we have performed next generation sequencing (NGS) using Illumina mi-seq. Using the sequence obtained, we have performed phylogenetic analysis from which we found that although the EfHV belongs to the sub-family of Gammaherpesvirus, it forms a distinct branch within the sub-family. In addition to that we have identified the different proteins present in the virion by performing mass spectroscopy and have found that the virion components are similar to other herpesviruses. We have also infected cells of different species with the EfHV to understand the spectrum of different species that this virus is capable of infecting and we have found that it is able to infect human, monkey, porcine and feline cell lines apart from the bat cell line. **Conclusions:** The phylogenetic analysis shows that EfHV is a distant relative of all other gammaherpesviruses known so far. It might have evolved together with the big brown bat. Further studies looking at the interaction of EfHV and big brown bat might help us understand more about the persistent infection in bats and their unique was of resisting cancer.

Experimental Infection of Jamaican Fruit Bats (*Artibeus jamaicensis)* with Zika Virus

Ashley Malmlov[1], Kaitlyn Miedema[1], Tawfik Aboellail[2], Corey Rosenberg[1], Miles Eckley[1], Nunya Chotiwan[1], Rebekah C. Gullberg[1], Rushika Perera[1] and Tony Schountz[1]

[1]Arthropod-Borne and Infectious Diseases Laboratory, Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, Colorado, USA and [2]Veterinary Diagnostic Laboratories, Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, Colorado, USA

Objectives: Zika virus (ZIKV) emerged in the New World with the 2014 outbreak in Brazil. It has spread to much of South America, Central America, Mexico and the Caribbean, with hundreds of thousands of cases. While disease presentation may be subclinical to mild and include symptoms of maculopapular rash, conjunctivitis, and arthralgia, infection of pregnant women can lead to fetal microcephaly. Additionally ZIKV infection can induce Guillain-Barre syndrome. In the 1950s and 1960s bat species were investigated as possible reservoirs for ZIKV. In total, five different species of bats were found to be susceptible to the virus. Bats seroconverted, had viremia,

and, in one experimental infection study bats developed fatal neurological disease. This warranted further investigation of ZIKV in bats to determine their use as an animal-model, and to better understand the potential role of bats in viral ecology. **Methods:** Nine Jamaican fruit bats (*Artibeus jamaicensis*) were subcutaneously inoculated with $7.5x10^5$ pfu of ZIKV strain PRVABC59 and monitored over the course of 28 days, during which there were no conspicuous signs of disease. Bats were euthanized at 2, 5, 10 and 28 days post-inoculation to assess the course of infection and antibody responses. **Results:** Bats seroconverted by day 28 by ELISA with ZIKV-infected, fixed Vero E6 cells. Low levels of viral RNA were detected in one brain and one urine sample. IHC detected ZIKV antigen in lung and testes of one bat, and brains and salivary gland of two others. Pathology was consistently observed in the lungs, heart, testes and brain. Pneumonia was observed in four bats, cardiomyocyte necrosis in three bats, degeneration and lymphocyte infiltration in the testes of two bats, and neuronal degeneration in the hypothalamus and cerebellum in three bats. **Conclusions:** These results provide evidence that Jamaican fruit bats are susceptible to ZIKV and may serve as an animal model to study neurological components and sexual transmission of the virus. Low viral load in urine and tissues suggests the role of bats in viral ecology may be minimal.

Long-term monitoring of *Bartonella* bacteria in a captive colony of fruit bats and experimental evidence of bat flies as vectors of bartonella

Clifton McKee[1,2], Colleen Webb[1], Michael Kosoy[2], Ying Bai[2], Lynn Osikowicz[2], Richard Suu-Ire[3], Yaa Ntiamoa-Baidu[4], Andrew Cunningham[5], James Wood[6], David Hayman[7]

[1]Department of Biology, Colorado State University; [2]Division of Vector-Borne Diseases, Centers for Disease Control and Prevention; [3]Wildlife Division, Forestry Commission of Ghana; [4]Department of Animal Biology and Conservation Science, University of Ghana; [5]Institute of Zoology, Zoological Society of London; [6]Department of Veterinary Medicine, University of Cambridge; [7]Institute of Veterinary, Animal and Biomedical Sciences, Massey University

Objectives: Few experimental studies have monitored long-term infection dynamics in bat populations. This is especially true for vector-borne bacteria, where there can be significant challenges in maintaining both host and vector populations in controlled settings. In order to understand the importance of vector populations in the long-term maintenance of infection prevalence and bacterial diversity, we advocate for the use of semi-natural, long-term experiments capable of detecting changes in infection dynamics linked to the force of infection by vectors. **Methods:** Using blood samples taken from a captive colony of ~100 fruit bats (*Eidolon helvum*) in Accra, Ghana from July 2009 - March 2012, we monitored the dynamics of *Bartonella* spp. infection in the bat population using molecular techniques. Over this period, the bat fly population (*Cyclopodia greefi*) infesting the captive bats declined, but was then supplemented with additional flies from wild *E. helvum* in January 2012. We hypothesized that prevalence and species diversity of *Bartonella* infections in the colony will vary with changes in the bat fly population. **Results:** *Bartonella* prevalence and diversity peaked in March 2010 with 77% of bats infected and 8 *Bartonella* spp. present, then began to decline until July 2011 with only 15% of bats infected and 4 *Bartonella* spp. present. After the reintroduction of flies in January 2012, prevalence increased to 43% in March 2012 with 6 species present. Bats that received flies were equally likely to become positive after January 2012 as bats that did not receive flies, which may be attributable to dispersal of flies among bats after reintroduction. Additionally, changes in relative *Bartonella* spp. abundances showed that the species lost over time were uncommon in bats, but some of these uncommon species became more abundant after the reintroduction of flies. **Conclusions:** This experiment indicates that *C. greefi* bat flies are likely vectors of bartonella in *E. helvum* and play an important role in the maintenance of bacterial diversity in bats. Ongoing occupancy modeling work will explore the influence of within-host processes (including bacterial interactions and host resistance to infection) and alternative transmission routes on the long-term infection dynamics in individual bats.

1. Predicting the epizootiology of temperate bat disease: Is it all about the bats?James N. Aegerter[1], Ashley C. Banyard[2], Anthony R. Fooks[2], Graham C. Smith[1]

[1]Animal and Plant Health Agency (National Wildlife Management Centre), Sand Hutton, York, UK. [2] Animal and Plant Health Agency (Weybridge), New Haw, Addlestone, UK

Predicting the dynamics of disease in wild bats, their epizootiology, and the risks these pose to people, the economy or other biodiversity is complicated. Bats may be the evolved hosts for disease, effective maintenance hosts, or accidental spill-over hosts (we cannot always distinguish which), whilst their unique life-style permits the exceptional natural movement of disease, as well as an exceptional potential to vector disease into homes, farms or other sensitive sites. These diseases may pose social or economic concerns (i.e. to public or livestock health), or produce conservation concerns. Further, diseases may well also be endemic, exotic or newly emerging, and importantly their dynamics today occur in the contexts of rapid land-use change and climate change. With decision-makers relying on the quality of epizootiological predictions, and substantial uncertainty about the pathogen, its pathology in wild bats, a changing environment, and the abstraction of these into mathematical form, it is surprising that little effort has been made to construct and validate mechanistically realistic models of bat populations to act as the solid foundation for higher-level disease modelling. Here we aim to produce a generic tool to provide some evidence based predictions of bat disease epizootiology, founded on a coherent representation of bat ecology and behaviour deployed through an IBM (Individual Bat Model). Importantly, this is founded on an independently validated understanding of their ecology and population dynamics, both of which need to emerge as model behaviour before disease is added. We recognise at least two divergent life-history strategies and lifestyles; ‘slow’ bats, typified by cave hibernators, include a seasonal hierarchical spatial and population structure; ‘fast’ bats show larger but less structured communities. Both accommodate the emerging understanding of bats as social animals as well as assuming that spatial heterogeneity drives some form of meta-population process. Early work has illustrated the surprising variation/instability in demographic structure driven by environmental variation close to range edges (many British bats are at their cold edge in the UK), as well as highlighting basic gaps in knowledge which are pivotal in robust predictions of disease dynamics (males in summer – Where? When? And how much?).

2. **Comparative loss of function screens highlight common cellular pathways required by mumps virus for replication in bats and humans**

Objectives: Bats have been implicated as an important source of new and emerging paramyxoviruses. The identification of bat-borne paramyxoviruses closely related to mammalian paramyxoviruses suggests a possible risk of zoonotic transmission of these paramyxoviruses. Mumps virus (MuV) a contagious virus of the genus *Rubulavirus*, was thought to be an exclusive human pathogen with no animal reservoir. Recently, the complete genomic sequence of a mumps-like rubulavirus was obtained from an African bat. In order to ascertain if bat and human cells are capable of supporting the replication of MuV, and to identify cellular proteins involved in the viral life cycle, we performed comparative genome scale siRNA screens using a human and novel bat siRNA library. **Methods**: Comparative genome scale siRNA screens with MuV were performed. The human MuV siRNA screen (Qiagen) was previously performed in our lab using A549 cells, a human lung adenocarcinoma cell line. A custom bat siRNA library was designed to target 18,328 genes of the *Pteropus alecto* genome. The bat siRNA screen was performed in PaKi cells, a *Pteropus alecto* kidney cell line. **Results**: The coatomer complex I, a known dependency factor was identified as required for MuV replication in both human and bat cells. Eukaryotic initiation factor 3 (eIF3) is a multiprotein complex that functions during the initiation phase of eukaryotic translation was also identified as a host factor. Interestingly, ABCE1, identified as a pan-paramyxovirus host factor, was not required for MuV replication in bat cells. **Conclusions**: This study is the first to utilize a bat genome scale siRNA screen and provides a novel overview of cellular proteins and pathways that impact this important pathogen.

3. **Implementation of a RT-PCR Assay to Detect Henipaviruses in Trinidad Bats**

Objectives: Since the emergence of Hendra in Australia, and Nipah in Malaysia and Bangladesh, evidence of henipaviruses in bats has been reported in Thailand, Cambodia, India, Papau New Guinea, China, and Madagascar. Cedar virus, a novel henipavirus, has been isolated from bats in Australia. There has been evidence of seropositivity among humans and *Eidolon helvum* (Straw-coloured fruit bat) bats in Cameroon, as well the publishing of the genome sequence of a henipa-like virus from a bat sample in Ghana. More recently, sequences related to henipaviruses were identified in New World bats, and Brazilian bats were found to have antibodies against henipa-like viruses, though no viral isolate has yet been obtained. This suggests that henipaviruses are likely to exist in other regions, including the Western hemisphere, presenting a need to investigate host populations. The goal of this study is to design a PCR assay to screen bat samples from Trinidad to detect novel henipa or henipa-like viruses.
Methods: Using published primer sets from Tong, et al, and van Boheemen, et al, PCR assays were developed to screen various tissue samples collected from bats in Trinidad. Both primer sets will be evaluated for their ability to detect henipaviruses using viral RNA standards for Hendra, Nipah Bangladesh, and Nipah Malaysia. The 132 samples are from 30 bats, including the species *Saccopteryx bilineata* (greater sac-winged bat), *Carollia perspicillata* (Seba's short-tailed bat), and *Artibeus planirostris* (Flat-faced fruit-eating bat) (sensu Larsen, 2007). Tissues harvested include brain, kidney, liver, spleen, lung, and fetal tissue.
Results: The PCR assay is able to detect viral RNA standards of Hendra, Nipah Bangladesh, and Nipah Malaysia. The assay will be further optimized to screen tissue samples. Samples that screen positive by this assay will be sequencinged.
Conclusions: To our knowledge, no henipaviruses have yet been detected or isolated from New world bats, though studies suggest their presence. Thus, screening for novel henipaviruses in Trinidad bats will help elucidate the full geographic range of these viruses, allowing a better understanding of risks of emergence and outbreaks in humans.

4. **Genomic characterization and pathogenic potential of a novel evolutionarily-divergent alphacoronavirus isolated from *M. lucifigus* bats in Alaska.**

Objectives: Coronaviruses (CoV) are zoonotic pathogens with the potential to cross species barriers from bats into other mammals, including marine mammals, swine and humans. Novel bat-origin coronaviruses have been responsible respiratory disease in humans, notably betacoronaviruses (OC43, HKU-1, SARS and MERS) and alphacoronaviruses (229E and NL63). Thus, it is important to identify the reservoirs of CoV in bats and their potential for transmission, and pathogenicity, in other mammalian species. We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus,* the little brown bat.

Methods: Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. Total RNA extracts were screened by RT-PCR with coronavirus primers matching CoV ORF1a, and amplicon sequencing. Complete genomes of novel viruses were sequenced by next-generation sequencing (NGS) RNA-seq.

Results: Sanger sequencing of amplicons confirmed the presence of an alphacoronavirus phylogentically related to persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. Primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. Aligning to a reference *M. lucifigus* virus from Colorado, bat alphacoronavirus CDPHE15/USA/2006, we assembled a full-length genome (28,515nt) identifying the novel alphacoronavirus/bat/Alaska/s7/2014. A high

degree of thermodynamically stable stem-loop RNA structures are predicted by Mfold within 700nt of 5' and 3' termini of genome**.** While nucleotide conservation to the Colorado virus was 96%, notable amino acid differences were identified in coronavirus proteins. The major CoV surface spike (S) protein exhibited 26 amino acid changes, including 14 in the globular head containing the putative receptor-binding domain, suggesting divergence based on immune evasion or receptor-specificity. Another 6 amino acids were altered in the fusion hinge. Protease cleavage sites were not conserved. Nucleoprotein (N) and ORF3 also exhibited amino acid differences.

Conclusions: Understanding the evolution and pathogenicity of this novel evolutionarily-divergent alphacoronavirus provides insight into the role of bats in virus transmission, and ecological assessment of bat-borne virus reservoirs in North American ecosystems.

5. Preliminary Evidence of Secondary Acquisition of Tymoviridae and Partitiviridae in Little Brown Bats (*Myotis lucifugus*) in Southcentral Alaska.

1 Dept. of Biological Sciences, University of Alaska Anchorage
2 Battelle Memorial Institute
3 National Center for Genome Resources, santa Fe NM
4 Dept. of Veterinary Medicine, University of Alaska Fairbanks

We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus,* the little brown bat. Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. Total RNA extracts were screened by RT-PCR and CoV ORF1a, and primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. Sanger sequencing of amplicons confirmed the presence of an alphacoronavirus phylogenetically related to persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. In two distinct bat samples, preliminary results indicate the likely presence of tymovirus (eg. Dulcama mottle virus) probably acquired through ingestion of insects feeding on infected plants. In addition, initial results indicate presence of β-partitivirus closely aligned to *Rosellina*-type associated with spruce/alder and other partitivirus-like sequences. Secondary acquisition of virus obtained by feeding or incidental infection by fungi (eg. γ-partitivirus associated with *P. destructans*) has been previously described for bats collected from similar ecological settings (eg. Thapa *et al.* 2016). We continue to further refine these initial for better resolution of the virome of Alaska bats.

6. Molecular Screening of Zika and Dengue Viruses in Bats (*Artibeus jamaicensis, Glossophaga longirostris* and *Molossus molossus*) from Grenada, West Indies.

Marcy Kanuka[1], Ashley Malmlov[2], Christine Cornish[1], Kathleen Parker[1], Cassandra Tang Wing[1], Diana Stone[1], Tony Schountz[2] and Sonia Cheetham[1]

[1]Department of Pathobiology, School of Veterinary Medicine, St. George's University, Grenada, West Indies; [2]Department of Microbiology, Immunology, and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Colorado, USA

Background: In recent years Zika virus (ZikV) has changed from an uncommon and poorly documented infection to a global public health concern. Dengue virus (DenV) has long-standing human health concerns worldwide, including Grenada, and has been detected in bats from other tropical countries. **Objective**: To determine if Grenada bats are infected with ZikV and DenV and thus possible reservoir hosts for these viruses. **Methods**: Forty-nine bats from 3 different genera and feeding behaviours (frugivorous, nectivorous and insectivorous) were trapped and humanly euthanized. ZikV RT-PCR was performed on serum, testes, spleen and brain samples, and a DenV RT-PCR multiplex was performed on serum. Amplicons of the expected sizes were sequenced for confirmation. **Results**: Physical exams prior to euthanasia and sample collection indicated all bats were clinically healthy. All 3 bat species collected tested positive for both viruses. Sera from 27 bats out of 41 tested were positive for ZikV (65.9%) and sera from 12 bats out of 19 tested were positive for DenV (63.2%). All DenV positive bats were infected with serotype 2, with one of these bats testing positive for both DenV serotype 2 and 4. Brains from 22 bats out of 48 tested were positive for ZikV (45.9%). Testes from 2 bats out of 12 tested were ZikV positive (16.7%) and a spleen from one bat out of 22 tested was ZikV positive (4.5%). **Conclusions**: The results demonstrate that frugivorous, nectivorous and insectivorous bats in Grenada are infected with both ZikV and DenV. Of interest is that despite many bats testing positive for ZikV in the brain, all bats appeared clinically healthy with no signs of neurologic dysfunction. Histopathology and immunohistochemistry are pending to

determine if infection is associated with lesions. Virus quantification is currently underway to determine if the level of viremia for either ZikV or DenV is high enough to consider the different bat species as potential reservoir hosts.

7. Serologic evaluation of Alphavirus and Flavivirus exposure in bats in Grenada

Diana Stone[1], Christine Cornish[1], Amy C. Lyons[2], Yan-Jang S. Huang[2], Dana L. Vanlandingham[2], Stephen Higgs[2], Bradley Blitvich[3], Abiodun A. Adesiyun[4], Sharlene Santana[5], Leith Leiser-Miller[5], Sonia Cheetham[1].

[3] Veterinary Microbiology and Preventive Medicine, College of Veterinary Medicine, Iowa State University, Iowa, USA
[4]Department of Basic Veterinary Sciences, School of Veterinary Medicine, University of the West Indies, Trinidad and Tobago.
[5]Department of Biology and Burke Museum of Natural History and Culture, University of Washington, Seattle, WA, USA.

Objective: Determine exposure to Alphaviruses and Flaviviruses in bats in Grenada. **Methods:** Fifty bats were trapped in August, 2015 in Grenada. Sera from all bats were tested for antibodies to flaviviruses: West Nile virus, Japanese Encephalitis virus, St. Louis Encephalitis virus, Bussuquara virus and dengue virus serotypes 1-4 (DENV-1,2,3,4) using the plaque reduction neutralization test (PRNT). Forty three of the 50 samples were tested for antibody to alphaviruses: Western Equine Encephalitis virus, Venezuelan Equine Encephalitis virus and Eastern Equine Encephalitis virus using epitope-blocking ELISA and 42 samples were tested for antibody to the alphavirus Chikungunya (CHIKV) using PRNT. **Results and Conclusions:** Two species of fruit bats were sampled, *Artibeus jamaicensis*, (48), and *A. lituratus*, (2). Fifteen of the 42 tested positive for neutralizing antibodies to CHIKV at $PRNT_{50}$ with titers 1:10 to 1:640. All 43 bats tested negative for epitope blocking antibody to the other alphaviruses except one positive for Venezuelan Equine Encephalitis virus. All 50 bats tested negative for neutralizing antibody to flaviviruses except one which had a Bussuquara virus $PRNT_{80}$ titer of 20. **Discussion:** Historically, DENV has been endemic in Grenada. CHIKV was introduced to the island in 2014. Bats for this study were trapped a year after the peak human CHIKV epidemic. Of interest is that in a separate study molecular detection confirmed the presence of both DENV and CHIKV RNA in bats serologically tested in this study. Of the 15 CHIKV seropositive bats, one was positive for CHIKV RNA. Of the 50 DENV seronegative bats, 6 showed detection of flavivirus RNA with a band compatible with DEN3. Thus, the negative DENV serology is unanticipated, but may reflect lack of neutralizing antibody responses developed for DENV. Future studies will characterize the humoral immune response to DENV in naturally exposed Grenada bats and determine whether non-neutralizing antibody responses are present. The type of immune response to DENV in bats may promote persistent infection and high-titer viremia and thus contribute to viral maintenance. Our results and those of the molecular study confirm that Grenada fruit bats are exposed to CHIKV and DENV, but their role in the epidemiology of these viruses is currently unknown.

8. **Isolation and molecular characterization of Bukakata orbivirus, a novel virus from a Ugandan bat, and associated pathology in experimentally infected Jamaican fruit bats (*Artibeus jamaicensis*)**

Fagre AC, Kityo R, Lee J, Mossel E, Crabtree, M, Nalikka B, Nakayiki T, Kerbis J, Gilbert, A, Bergren, N, Nyakarahuka L, Lutwama J, Stenglein M, Byas A, Malmlov A, Bergren N, Rice L, Miller B, Schountz T & Kading, RC.

Objectives: In 2013, a novel orbivirus (*Reoviridae: Orbivirus*) was isolated from an Egyptian fruit bat (*Rousettus aegyptiacus*) in Uganda. Preliminarily named "Bukatata orbivirus" after the region where the infected bat was captured, this virus is the fourth identified orbivirus of bats. The genomes of all four bat orbiviruses (Bukakata, Ife, Fomede, and Japanaut viruses) were sequenced to assess their phylogenetic placement within the genus *Orbivirus*, and develop hypotheses regarding virus-vector associations. **Methods:** Whole genomes of all four viruses were sequenced using an Illumina platform and assembled *de novo*. To begin studying the effect of infection with Bukakata orbivirus on a bat host, three male Jamaican fruit bats (*Artibeus jamaicensis*) were inoculated intraperitoneally with 5.3 $\log_{10}$ pfu Bukakata orbivirus and monitored daily for signs of clinical disease. **Results:** Phylogenetic analysis placed Fomede and Bukakata orbiviruses in the tick-borne clade, and Japanaut and Ife in the mosquito/*Culicoides* clade. On day 12, all three bats were diffusely hyperemic and tachypneic and, thus, were humanely euthanized. Histopathologic lesions of perivascular inflammation, hemorrhage and edema were present in varying degree of severity in the liver, lung and kidney of all three bats. Additional lesions included meningeal hemorrhage in two of the bats and evidence suggestive of early hepatic vasculitis in the other. Eosinophilic and suppurative gastroenteritis affected all bats with one containing intraluminal bacilli, suggesting secondary bacterial infection. **Conclusions:** Immunohistochemistry and qPCR will be performed to assess

relative abundance of virus in various organ systems to optimize future analyses. Future experimental infections will be performed to monitor temperature, physiological and immune parameters, virus shedding and viremia throughout the course of infection. These preliminary data are critical in the assessment of the potential role of bats as reservoirs for arboviruses.

9. **Using GIS to Guide Ebola Virus Disease Ecology Field Investigations**

Robert J. Fischer[1], Seth D. Judson[1,2], Sarah H. Olson[3], Vincent J. Munster[1]
[1]Virus Ecology Unit, Laboratory of Virology, Rocky Mountain Laboratories, NIAID, NIH Hamilton, MT; [2]David Geffen School of Medicine at UCLA, Los Angeles, California; [3]Wildlife Conservation Society, Bronx, New York

Objectives: In the health field GIS is being used to track epidemics in real time and to create predictive models of outbreak potential. We have investigated the feasibility of using a maximum entropy model (Maxent) to assist in determining the target species and optimum locations and times to direct field sampling efforts. **Methods:** We developed an ecological niche model of Ebola virus (EBOV) using the location of Ebola virus disease (EVD) outbreak index cases as presence points we developed an ecological niche model to predict geographic locations that had environmental conditions similar to those of known outbreaks. To determine which environmental parameters were important in constructing the model, a correlation matrix was constructed using ArcGIS and highly correlative parameters were eliminated and the model reconstructed. Additionally, home ranges of African mammals were overlaid on a map and compared to the model to determine which species inhabit the geographical regions predicted to be suitable for a spillover event. **Results:** The model was used to highlight environmental factors common to the location of the EVD index cases from 19 environmental parameters and altitude that were used to construct the model. A list of 66 mammals including 26 bat species with home ranges that overlap the modeled range of EBOV was produced. **Conclusions:** While there is no conclusive evidence that bats serve as the reservoir for Ebola virus (EBOV) i.e. there is no wild EBOV bat isolate, there is evidence that they may play a role in maintaining the virus in nature. Combining what is known about the natural histories of bat species and animal species known to be susceptible to EVD such as great apes, duikers and forest hogs coupled with environmental factors predicted to be important, we can further prediction when and where spillover events may occur and tailor our sampling efforts to target these conditions. Additionally, as there is a dearth of knowledge on the natural history of deep forest fruit bats we are planning to monitor the short term daily movements of *Hypsignathus monstrosus* with the aim of being able to predict where the movements of the bats and susceptible species may commonly intersect.

10. **Bat - infection interactions: Signals of evolution, ecology, immunity and deforestation**

Hannah Frank[1], David Enard[1], Chase Mendenhall[1,2,3], Ji-Yeun Lee[4], Ellie Armstrong[1], Stefan Prost[1], Seth Judson[5], Jamieson O'Marr[1], Gretchen Daily[1,3,6], Dmitri Petrov[1], Scott Boyd[4] and Elizabeth Hadly[1,6,7]

[1] Department of Biology, Stanford University; [2] The Nature Conservancy; [3] Center for Conservation Biology, Department of Biology, Stanford University; [4] Department of Pathology, Stanford University; [5] David Geffen School of Medicine, University of California, Los Angeles; [6] Stanford Woods Institute for the Environment, Stanford University; [7] Center for Innovation in Global Health, Stanford University

Objectives: Bats are ecologically diverse and these ecological differences may lead to differences in infection prevalence and identity. We sought to discover the evolutionary and ecological signatures of differences in bat behavior and environment on bat-infection patterns, as well as to understand how these patterns are impacted by human activity. Regions where a high diversity of hosts occur with prevalent deforestation, human habitation and livestock rearing are of great concern for potential spillover. Accordingly, we aimed to characterize infections of potential spillover importance in an altered landscape. **Methods**: Using a combination of genomics, targeted sequence capture and tests of positive selection, we screened 60 species of bats distributed globally for evidence of selection in response to viruses. Additionally, we screened the speciose and ecologically diverse bat fauna of an agricultural landscape in Costa Rica for eight viral groups (Herpesviridae, Astroviridae, Adenoviridae, Paramyxoviridae, Coronaviridae, *Lyssavirus*, Filoviridae, Influenza A), *Bartonella* bacteria and ectoparasites to detect pathogen sharing, immunological and behavioral patterns of infection and the impact of humans on these relationships. **Results**: Evolutionarily, viral sharing has been important for shaping bat immune evolution. However, ecologically most infections are host specific and regulated by host immunity with species that are more frequently exposed less likely to yield detectable pathogen nucleic acids. In deforested areas, these patterns shift in a sex-specific manner, disproportionately impacting females with potential for population stability. **Conclusions**: This study yields evolutionary insights into the unique relationship between bats and viruses, identifying the environmental factors that are driving adaptation. Additionally, it represents one of the broadest infection screening studies in the Neotropics, which has the highest density of bat diversity but is less frequently screened than the Old World. Our data suggest that there are few pathogens of spillover concern circulating in this landscape, but that humans may be having a detrimental impact on bat health.

Daytime behavior of *Pteropus vampyrus* and *Acerodon jubatus* in the natural habitats: a cue of viral transmission

Arifin[6], Yasushige Ohmori[1], Ken Maeda[3], Srihadi Agungpriyono[2] and Eiichi Hondo[1]

[1]Graduate School of Bioagricultural Sciences, Nagoya University; [2]Faculty of Veterinary Medicine, Bogor Agricultural University; [3]Joint Faculty of Veterinary Medicine, Yamaguchi University; [4]Research Center for Biology, Indonesian Institute of Science, Indonesia; [5]Japan International Cooperation Agency; [6]Livestock, Fisheries and Marine Services, Indonesia

Objectives: The large flying fox (*Pteropus vampyrus*) are well-recognized host of Nipah virus. Base on serologic studies, the golden-crowned flying fox (*Acerodon jubatus*) are infected with Ebola Reston virus. To estimate the risk of disease emergence, it is important to understand the behavior of flying foxes. This study aimed to clarify diurnal behavior of *P. vampyrus* in Leuweung Sancang conservation area, Indonesia (7º 43′ 45.12″ S, 107º 54′ 10.08″ E), and *A. jubatus* in the Subic Bay Freeport, the Philippines (14º 46′ 31.54″ N, 120º 19′ 14.90″ E). **Methods:** Quantitative behavioral data were collected using instantaneous scan sampling and all occurrence focal sampling methods. **Results:** Unexpectedly, many flying foxes were awake during daytime (*P. vampyrus*: 46.9 ± 10.6%, *A. jubatus*: 23.7 ± 3.1% of scanned bats), and showed various activities. The commonly observed behavior were wing flapping and self-grooming behaviors. Males engaged in sexual activity more than females (*P. vampyrus*: 6.5 ± 1.6 % in males and 0.2 ± 0.1 in females, *A. jubatus*: 1.6 ± 0.5 % in males, 0% in females), sometimes accompanying with aggression behaviors between males and females. There was no significant difference in negative social behaviors (fighting and wing spreading) between males and females of *P. vampyrus*, whereas, the difference was found in *A. jubatus* (2.6 ± 0.7 % in males, 0.1 ± 0.04 % in females). The positive social behaviors (maternal care, mutual grooming and playing) were rarely found in *P. vampyrus*, but never in *A. jubatus*. Physical communications, not only among flying foxes, but also direct and/or indirect contacts between *P. vampyrus* and non-human primate (*Trachypithecus auratus*) were observed (3.3 ± 0.5 times per day). Specifically, periodic disturbance by tourists and unidentified aerial predators like raptors was observed at the roosting site of *A. jubatus*. *A. jubatus* shared the same roosting site with *P. vampyrus*, this enables the contacts between the two species of flying foxes, an average 25.4 ± 6.3 times per day. **Conclusions:** These observations would provide a cue to know how viral transmissions among flying foxes, other wildlife and humans in South-East Asia.

12. The study of whole spike gene of bat coronavirus from Thailand using Next Generation Sequencing

Yutthana Joyjinda[1], Supaporn Wacharapluesadee[1], Prateep Duengkae[2] , Apaporn Rodpan[1], Teerada ponpinit[1], Thongchai Kaewpom[1], Sangchai Yingsakmongkol[3], Kevin J Olival[4], Thiravat Hemachudha[1]

[1] The Thai Red Cross Emerging Infectious Disease Health Science Centre and World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of medicine, Chulalongkorn University, Thailand, [2] Forest Biology Department, Faculty of Forestry, Kasetsart University, Thailand, [3] Faculty of Veterinary Medicine, Department of Microbiology and Immunology, Kasetsart University, Thailand, [4]EcoHealth Alliance, New York, NY, USA

Objectives Bats have been recognized as the natural reservoirs of a vast variety of viruses, including as host to Coronaviruses – a viral family of public health importance. Bat coronaviruses have been intensively studied since the discovery of Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV) and have expanded even more after the emergence of Middle East Respiratory Syndrome Coronavirus (MERS-CoV), both of which are purposed to have originated from bats. Since spike protein is correlated with host cell receptor binding and membrane fusion, a better understanding of sequence diversity for this gene will help determine the potential for host-switching and zoonotic potential of CoVs. The aim of our study was to characterize the spike gene of bat coronaviruses from Thailand. **Methods** we PCR amplify about 4 kb of whole spike gene from seven PCR positive coronavirus of *M. magneter* and *R. shameli* bats from northern part of Thailand and sequencing using Next Generation Sequencing (NGS). Phylogenetic tree of the full alignment of whole spike gene sequences was estimated by maximum likelihood method. **Results** The average of 1,306,845 sequences of spike gene per sample was obtained from NGS. Phylogenetic tree of all seven spike sequences are grouped into the same clade in the alpha Coronavirus (α CoV) and mostly related to the Bat Coronavirus-1A (BatCoV-1A). **Conclusions** Even though seven spike genes of coronaviruses in this study showed sequence different from emerging disease beta coronavirus group B and C (β CoV B and β CoV C); nevertheless, more positive bat coronaviruses should be investigated including whole genome sequencing of bat coronaviruses that may useful for more understanding host-viral evolution and potential for host switching or spillover.

13. **Assessment of the cross-species potential of two emerging coronaviruses, SARS-CoV and MERS-CoV, by Protein-Protein Molecular Docking analyses**
Jun Li & Vincent Munster

Laboratory of Virology, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health

Objectives: Coronaviruses are a virus family with broad host range, and have spilled over from their natural reservoirs into various mammalian species, including humans. For humans, four of them cause common cold and circulate exclusively in the human population. In addition, SARS-CoV and MERS-CoV, recently emerged in the human population and are associated with severe respiratory illness. Where do these zoonotic viruses come from, and how did they cross the species barrier? These questions are generally difficult to address. The critical residues at interaction interface of host receptors (DPP4 for MERS-CoV and ACE2 for SARS-CoV) are believed to impact the binding ability of the receptors with viruses' surface-located spike. The diversity of available protein sequences limits our understanding of the receptor-mediated pathogen-host interactions for bat coronaviruses. Computational molecular docking is a bioinformatics tool, which allows us to explore the potential receptor-spike interactions in silico. The aim of this study is to analyze the diversity of SARS-CoV and MERS-CoV receptors from different mammalian hosts, to predict the host range using modeling and molecular docking. **Methods:** Up to 109 DPP4 and 94 ACE2 sequences from mammalian hosts were downloaded from genbank or acquired by sequencing, covering 60 and 51 different families respectively. The putative crystal structures were homologically modeled, and protein-protein docking was performed using Autodock Vina on NIH HPC Biowulf cluster. **Results:** Both of DPP4 and ACE2 receptors sequences from the hosts have relative high diversity. The docking results point out wide but family specific of host range of MERS-CoV and SARS-CoV. Virtual mutagenesis studies explored the impact of each critical residue of DPP4 on binding interaction for *Homo sapiens*, *Mesocricetus auratus*, *Desmodus rotundus*, *Canis lupus familiaris* and *Felis catus*. **Conclusions:** Although currently in silico analysis of spike-receptor interactions utilizing molecular docking methods still are in its early stages of development, the generated results could be utilized to perform large screens of potential virus reservoir, and intermediate hosts associated with emerging coronaviruses, and could potentially be utilized to estimate the distribution of MERS-CoV and SARS-CoV in ecosystems.

14. **Hendra virus phylogeography in eastern Australia**
Kessler MK[1], Kamath PL[2], Smith CS[3], Goldspink LK[3], Plowright RK[1]

[1] Department of Microbiology and Immunology, Montana State University, Bozeman, Montana, USA; [2] U.S. Geological Survey, Northern Rocky Mountain Science Center, Bozeman, Montana USA; [3] Queensland Center for Emerging Infectious Diseases, Biosecurity Queensland, Department of Agriculture and Fisheries, Brisbane, Queensland, Australia

Objectives: Hendra virus (HeV) is an emerging zoonotic paramyxovirus that causes sporadic fatal disease in horses and humans in mainland Australia. Australian flying foxes (*Pteropus* spp. fruit bats), the endemic host, are gregarious, semi-migratory species that occupy the tropical and subtropical forests of coastal Australia. Despite the vast range of flying foxes, current outbreaks of Hendra virus have been restricted to a narrow band in southeast Queensland and northern New South Wales. Transmission dynamics of HeV between flying foxes is poorly understood, which limits our ability to identify potential points for management and spillover prevention. We used a phylogeographic framework to explore the spatial structure of HeV over eastern Australia, and to investigate factors that contribute to maintenance and spread of HeV in flying foxes. **Methods:** A three-year surveillance field study was initiated to improve understanding of Hendra virus diversity and disease dynamics in wild flying foxes, generating partial sequences from 26 colonies across eastern Australia. We incorporated sequenced isolates from spillover events in horses, and applied discrete and continuous Bayesian phylogenetic approaches to explore patterns in the dynamics and spatial spread of Hendra virus. Analysis was performed on a 2015 bp intergenic region between the nucleoprotein and phosphoprotein genes. **Results**: Preliminary analysis indicates a broad spatial structure, with lineages clustering loosely in space and time. However, we also find that multiple variants co-circulate in one colony at any given time, and that identical variants may co-circulate in geographically disparate colonies. Our ongoing approach is to identify drivers in the spatial spread and diversity of Hendra virus by examining the role species composition, roost structure, and migratory behavior play in shaping the geneology of Hendra virus. **Conclusions**: These data suggest that host factors (e.g., species composition within roosts) and/or environmental factors may play a role in HeV circulation within and between bat colonies. This work represents a novel approach to understanding the transmission dynamics and evolution of Hendra virus, as well as the functional connectivity of flying fox populations in eastern Australia.

15. **Viral Zoonosis in Georgian Bats**

Tamar Kutateladze[1], Lela Urushadze[1,3], Davit Putkaradze[1], Magda Dgebuadze[1], Giorgi Babuadze[1], Ioseb Natradze[3], Lillian Orciari[2], and AndresVelasco-Villa[2]

[1] National Center for Disease Control and Public Health Lugar Center, Georgia;
[2] CDC Atlanta, USA; [3]Ilia State University, Georgia

Objectives: Bats are reservoir-hosts of viral agents (lyssaviruses, paramyxoviruses, coronaviruses, and filoviruses), which are transmittable to humans and other animals. There are few bat virus detection studies linked to the Caucasus region. In Georgia, bat *Lyssavirus* (Rabies virus) is listed as a priority pathogen, and West Caucasian Bat Virus (WCBV) is the most genetically different member of the *Lyssavirus* genus. The goal of our study was to find WCBV and the newly discovered bat Coronavirus (bat-CoV) in Georgian bats. **Methods:** Bats that were used for sampling were collected in 2012 from four different regions in Georgia. Bat brains (n=236) were sampled and tested for the presence of lyssavirus antigen by the direct fluorescent antibody (DFA) test. A total of 186 bats of 11 different species were sampled for CoV confirmation. RT-PCR amplification assay targeting the 180 bp fragment within the RNA-dependent RNA polymerase RdRp gene and sequencing of the amplified product was used to confirm the presence of coronaviruses in bat specimens. The PCR product was sequenced on an ABI 3130 Automatic Sequencer. **Results:** None of the bats had detectable antigen consistent with an active infection of related *Lyssavirus* or WCBV. We found an outstanding diversity of CoV strains in Georgia; 54 bats tested positive for CoV. Sequence analysis demonstrated 97- 99% identity to five different types of CoV available at NCBI database. Most CoV positive bats were collected from Imereti, which is located in western Georgia. Bats with a higher prevalence of CoV were *Myotis blhytii* and *Rhinolophus ferrumequinum.* **Conclusions:** Our study revealed that we need additional research for excluding the existence of WCBV in Georgian bats. Future work will include determining the prevalence of rabies virus in these bat samples. To do this, we will perform rabies virus neutralization “Rabies Vaccine Response End-Point Titer (RFFIT)” assays. This was the first study addressing the genetic diversity of bat-CoV in this region. Further analyses and interpretation of the phylogenetic results for CoV will be a benefit for surveillance, system control, and response measures of emerging pathogens in Georgia.

16. Forestalling Future Outbreaks: Enhancing Capacity for Surveillance of Viral Hemorrhagic Fever Viruses in Sierra Leone

Aiah Lebbie[1], Jonathan Towner[2], Ibrahim Bakarr[3], Brian Amman[2], Amy Schuh[2], Jonathan Johnny[3], Tara Sealy[2], James Graziano[2], Celine Taboy[2], John Klena[2], Immah Conteh[1], Stuart Nichol[2], Alusine Koroma[1], Ibrahim Foday[1]and Richard Wadsworth[1]

[1]Department of Biological Sciences, Njala University, Sierra Leone, [2]Centers for Disease Control & Prevention, Atlanta, Georgia, USA, [3]Department of Wildlife Management, Njala University, Sierra Leone

Objectives: The first outbreak of Ebola virus disease in Sierra Leone exposed the limited in-country capacity for effective disease surveillance. Heavy reliance was placed on international support for human, technical and material resources. While the source of the outbreak has not been confirmed, human interactions with wildlife and their habitats continue unabated, raising fears of future outbreaks of zoonotic diseases. Building national level capacity, especially in research universities, would enhance Sierra Leone’s capability to forestall future outbreaks involving viral pathogens of public health concern. **Methods:** Through a collaborative agreement with the Viral Special Pathogens Branch at the Centers for Disease Control & Prevention, staff and students at Njala University have received field and laboratory training in ecological surveillance and molecular diagnosis of hemorrhagic fever viruses in bat populations. **Results:** Training in safe capture techniques, collection of blood/serum samples, necropsy techniques and the safe processing and storage of tissues specimens have been achieved over a period of 18 months for 12 Njala University staff and students. Further, three additional staff and students have been trained in molecular diagnostics using robotic nucleic acid extraction and qRT-PCR methods. These trainings, coupled with the acquisition of laboratory and field equipment and renovations of laboratory space on the Njala University campus and its field research station, are resulting in the inclusion of ecological surveillance and molecular diagnostics of viral pathogens in wildlife populations in the curriculum of Njala University in Sierra Leone. **Conclusions:** Strengthening technical and human capacity for disease surveillance in bats through long-term partnerships with research institutions could lay the foundation for preventing future outbreaks of global concerns.

17. Ecological aspects of bats in a cave frequented by members of the local community in Kaptum Cave in eastern Uganda.

Matovu Benard[1] (Graduate student), Nalikka Betty[2] and Kityo Robert[3]

Makerere University, College of Natural Science – Department of Zoology, Entomology and Fisheries Science Kampala Uganda

Few studies have addressed the ecology of cave bats in Uganda. This study assessed the diversity, roosting and feeding ecology, of micro bats (order *chiroptera*) as well as influence and frequency of human disturbance, in Kaptum cave of Eastern Uganda. Field observations were conducted between July/Augst 2016 and October/ November 2016 to document aspects of roost utilisation by the bats, their feeding choices and human influences on the cave in which 6 species of microchiropteran bats roosted. We used Mist nets and a Harp trap to capture individuals for examination and identification of species present. Infrared Trail trap Cameras were used to monitor roosting habits and activity patterns of the bats in the cave. A portable whether station was used to record the microclimatic conditions in the different sections of the cave in which the bats roosted to evaluate if there was any influence on choice roost. Kaptum cave has 6 species of insectivorous bats which seemed to prefer different sections of the cave. From evidence of insect remains in the roost, the diet of the bats in Kaptum cave consisted of eight insect orders (*Lepidoptera, Coleoptera, Orthoptera, Dictyoptera, Heymenoptera, Isopteran, Hemiptera, and Odonata*) with the order *Lepidoptera* constituting the bulk of insects preyed upon. At the moment we cannot separate the diet of the different species, since most insect remains were recovered in a section the cave we refer to as the Nycteris corner, because it was most used by these bats, but other species of Rhinolophids and Hipposiderids also frequented this corner in any 24hr period. We believe that the continued human presence in the cave could have implications for roost stability, but also could predispose the humans to potentially harmful aerosols associated with bats and bat guano.

18. **Middle East respiratory syndrome coronavirus spike plasticity in the context of the common vampire bat (*Desmodus rotundus*) DPP4 receptor.**

Rebekah McMinn[1], Michael Letko[1], Neeltje van Doremalen[1], Kerri Miazgowicz[2], Vincent Munster[1]

[1]Laboratory of Virology, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health [2]Department of Infectious Diseases, College of Veterinary Medicine, University of Georgia

Objectives: In 2012, a novel coronavirus, Middle East respiratory syndrome coronavirus (MERS-CoV), was discovered in humans and dromedary camels, although genetic evidence supports a bat ancestor. This range of animal hosts lead us to hypothesize that MERS-CoV can readily adapt to new hosts. The receptor for MERS-CoV, dipeptidyl peptidase 4 (DPP4) has previously been shown to act as a species barrier. By passing the virus over time on cells stably expressing the common vampire bat (*Desmodus rotundus*) DPP4 receptor, which MERS-CoV binds inefficiently, we will determine how potential adaptation in the spike glycoprotein may influence species tropism. **Methods:** We have compared the growth kinetics of MERS-CoV over 72hrs between different bat DPP4 receptors transfected on baby hamster kidney (BHK) cells, which are naturally unsusceptible to MERS-CoV. We then generated BHK cell lines stably expressing the *D. rotundus* DPP4 receptor. By passing MERS-CoV on these cells over time, we hope to observe adaptations in the viral spike protein that allow more efficient viral growth kinetics. Viral genomes containing the relevant mutations can be created through a reverse genetics system and tested for binding affinity and growth potential. **Results:** We show here that MERS-CoV can use DPP4 from different animal hosts, including a variety of bat species. Notably, MERS-CoV can bind and replicate using the *D. rotundus* DPP4 but very inefficiently compared to human DPP4, leading to delayed growth. We observed that MERS-CoV growth on cells stably expressing D. rotundus DPP4 displays a similar inefficient growth pattern as seen previously using a transfection method. **Conclusions:** Our data demonstrates that MERS-CoV can use a diverse set of host species receptors. Although we have successfully generated BHK cells stably expressing *D. rotundus* DPP4, sequencing of the MERS-CoV spike over many passages is needed to identify relevant mutations. The ability of the MERS-CoV spike to adapt to diverse host species receptors may play a significant role in cross-species transmission.

19. **Viral community dynamics of Australian Flying foxes**

Alison J. Peel[1], Victoria Boyd[2], Raina K. Plowright[3], Olivier Restif[4], Gary Crameri[2], John Giles[1], Hamish McCallum[1], Konstans Wells[1]

[1] Environmental Futures Research Institute, Griffith University, Queensland, Australia; [2] CSIRO Australian Animal Health Laboratory (AAHL), Geelong, Victoria, Australia; [3] Montana State University, Department of Microbiology and Immunology, Bozeman, MT, USA; [4] Department of Veterinary Medicine, University of Cambridge, Cambridge, UK

Objectives: Bats are reservoirs for a disproportionate number of zoonotic viruses, with spillover to people and domestic animals resulting in significant public health implications globally. In Australia, bat viral research has largely focused on Hendra virus, yet a diverse viral community has been detected in Australian Pteropid fruit bats (flying-foxes)[1,2]. Additionally, while the four Australian flying fox are capable of being infected with Hendra virus, not all species appear to be equally competent hosts[3,4]. In this context, interactions among co-infecting viruses and the dynamical consequences of these interactions are under- studied. We aimed to gain further insight into bat viral transmission dynamics by exploring dynamics within a multi-host-multi-pathogen framework. **Methods:** To characterise existing knowledge of the bat viral-host community in Australian flying foxes, a systematic literature review of published studies was undertaken and then complimented with additional unpublished data. Using urine samples collected from three of the four Australian flying-fox species in a related field study[6], we utilised a novel high-throughput multiplex PCR[5] to simultaneously detect up to 11 known bat paramyxoviruses. Within a Bayesian framework, we then modelled the monthly presence of different virus species at the roost level in relation to environmental drivers and the co-occurrence of other virus species. **Results:** Results support synchronous shedding pulses of multiple viruses, with significant co-circulation associations between certain virus species. **Conclusions:** Natural host-virus systems comprise complex communities, and our study explores how moving beyond single-pathogen-single host studies of bat pathogen dynamics towards broader consideration of the biotic interactions within viral and reservoir communities could progress our understanding of transmission and spillover of bat pathogens.

20. **The glycoprotein of Nipah virus in Thai bats associated with Nipah virus in Bangladesh**

Ponpinit T[1], Wacharapluesadee S[1], Duengkae P[2], Kaewpom T[1], Yinsakmongkon S[3], Rodpan A[1], Hemachudha T[1]

[1] World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University, [2]Faculty of Forestry, Kasetsart University, [3]Faculty of Veterinary Medicine, Kasetsart University

Objectives Bats have been recognised as a natural reservoirs of a large number of viruses including Nipah virus (NiV) and are associated with human activities which plays important role in the transmission of pathogens from bats to human. Study the glycoprotein NiV protein which plays important role in virus entry into host cells is a crucial in order to know the virus transmission. **Methods** Bat urine were collected from Luang Phrommawat temple, Chonburi province and screened for NiV nucleocapsid by using hemi-nested RT-PCR. The NiV positive urine samples were amplified the whole glycoprotein gene (1.8 kb). The whole sequences of nucleotide and amino acid of NiV glycoprotein were compared with sequences from both Malaysian and Bangladeshi strains from bats and humans. The phylogenetic tree was constructed by comparing amino acid sequence between NiV from Thai bat and NiV Bangladeshi patient. **Results** NiV glycoprotein sequence from Thai bats were homologous with Bangladeshi strain compared to the Malaysian strain. Furthermore, it shared 99.2-100% and 99.2-99.5% identity with nucleotide sequence of NiV glycoprotein from Bangladeshi bats and Bangladeshi patients, respectively. Amino acid sequence of NiV glycoprotein from Thai bats shared 99.8-100% and 99.5-99.7% identity with Bangladeshi bats and Bangladeshi patients, respectively. While, nucleotide sequence of NiV glycoprotein in Thai bats shared only 93.0-93.3% and 93.2% identity with Malaysian bats and Malaysian patients, respectively. Like nucleotide sequence, the amino acid sequence of NiV Thai bats shared only 95.7-96.0% and 95.7% identity with Malaysian bats and Malaysian patients. Phylogenetic analysis of NiV glycoprotein amino acid revealed that the NiV glycoprotein in Thai bats belonged to Bangladeshi patients. **Conclusions** This is the first step to understand the mechanism of NiV entry to the host. The results may indicates that NiV Thai bat strain has the potential to cause infection in humans. NiV glycoprotein and host receptors should be further investigated in order to understand the viral entry mechanism, host range, including intra- and cross-species transmission. Understanding the transmission of NiV from bats to humans is crucial in order to predict and prevent NiV outbreaks.

21. **Genomic characterization and pathogenic potential of a novel evolutionarily-divergent alphacoronavirus isolated from *M. lucifigus* bats in Alaska.**

Jonathan C. Rupp[1], Maegan Lange[1], Megan Howard[2], Anitha Sundarajan[3], Jonny Sena[3], Faye D. Schilkey[3], Molly Murphy[4], Douglas Causey[1], Eric Bortz[1].

[1]Dept. of Biological Sciences, University of Alaska Anchorage; [2]Battelle Memorial Institute; [3]National Center for Genome Resources, santa Fe NM [4]Dept. of Veterinary Medicine, University of Alaska Fairbanks

Coronaviruses (CoV) are zoonotic pathogens with the potential to cross species barriers from bats into other mammals, including marine mammals, swine and humans. Novel bat-origin coronaviruses have been responsible respiratory disease in humans, notably betacoronaviruses (OC43, HKU-1, SARS and MERS) and alphacoronaviruses (229E and NL63). Thus, it is important to identify the reservoirs of CoV in bats and their potential for transmission, and pathogenicity, in other mammalian species. We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus,* the little brown bat. Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. Total RNA extracts were screened by RT-PCR with coronavirus primers matching CoV ORF1a, and Sanger sequencing of amplicons confirmed the presence of an alphacoronavirus phylogentically related to persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. Primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. Aligning to a reference *M. lucifigus* virus from Colorado, bat alphacoronavirus CDPHE15/USA/2006, we assembled a full-length genome (28,515nt) identifying the novel alphacoronavirus/bat/Alaska/s7/2014. A high degree of thermodynamically stable stem-loop RNA structures are predicted by Mfold within 700nt of 5' and 3' termini of genome**.** While nucleotide conservation to the Colorado virus was 96%, notable amino acid differences were identified in coronavirus proteins. The major CoV surface spike (S) protein exhibited 26 amino acid changes, including 14 in the globular head containing the putative receptor-binding domain, suggesting divergence based on immune evasion or receptor-specificity. Another 6 amino acids were altered in the fusion hinge. Protease cleavage sites were not conserved. Nucleoprotein (N) and ORF3 also exhibited amino acid differences. Understanding the evolution and pathogenicity of this novel alphacoronavirus provides insight into the role of bats in virus transmission, and ecological assessment of bat-borne virus reservoirs in North American ecosystems.

22. **Spatial pattern of genetic diversity and selection in the MHC class II DRB of three Neotropical bat species**

Salmier A., de Thoisy B., Crouau-Roy B., Lacoste V. and Lavergne A.

Host–pathogen interactions—greatly influenced by environmental characteristics—are a major determinant of the extensive polymorphism of the Major histocompatibility complex (MHC) genes that play an important role in both resistance and susceptibility to diseases. Amazonia encompasses the greatest bat richness, as well as great landscape diversity. However, there are few studies regarding adaptation to infectious diseases of bats and even less in contrasting environmental conditions. We analyzed the genetic variability and positive selection signatures of the expressed MHC class II *DRB* exon 2 in three sympatric Amazonian bat species, *Carollia perspicillata*, *Desmodus rotundus*, and *Molossus molossus* inhabiting different environments (*e.g.*, forests, edge habitats, and urban areas). The role of the environment on the allelic composition and distribution of the *DRB* gene, as well as the effects of pathogen-mediated selection, recombination, gene conversion, demographic history and population structure on the MHC diversity were investigated. Overall, we identified 23 *DRB* alleles in 19 *C. perspicillata*, 30 *DRB* alleles in 35 *D. rotundus* and 20 *DRB* alleles in 28 *M. molossus*. We found clear evidence of at least two functional *DRB* loci as well as a trans-species mode of evolution within the Phyllostomidae family. Bats inhabiting forest environments presented higher number of alleles, revealing a heterozygote advantage likely associated with higher diversity of microorganisms in forest environments due to greater host species richness and better transmission-promoting parameters compared to disturbed environments. The *DRB* polymorphism was high in all sampling sites and for all species but different signatures of positive selection were detected depending on the environment, suggesting a local adaptation characteristic driven by an area-limited pathogen-mediated selection. The patterns of *DRB* diversity were similar to those of neutral markers for *C. perspicillata* and *M. molossus* while these patterns were different for *D. rotundus* for which a geographical structure was highlighted. These results supported that demographic process acts as an additional force in shaping *DRB* diversity. However, in structured populations, environmental constraints associated with characteristic pathogen pressures are the main drivers of MHC diversity.

23. Establishing a field collection scheme to investigate the role of African fruit bats as the natural reservoir of ebolaviruses

Ken Cameron[1], **Stephanie Seifert[2]**, Shauna Milne-Price[2], Alain Ondzie[1], Trent Bushmaker[2], Jean-Vivien Mombouli[3], Sarah Olson[1] and Vincent J. Munster[2]

[1]Wildlife Conservation Society, 2300 Southern Boulevard, Bronx NY, USA2
[2]Laboratory of Virology, Virus Ecology Unit, Division of Intramural Research, National Institutes of Allergy and Infectious Diseases, National Institutes of Health, Rocky Mountain Laboratories, Hamilton, USA
[3]Laboratoire National de Santé Publique, Brazzaville, Republic of Congo

Objectives: Filoviruses are among the most well-known and well-studied zoonotic pathogens, yet we know little about filovirus populations in their natural reservoirs. Phylogeographic and population genetic studies of filoviruses isolated from their natural reservoirs would shed light on the population structure and evolutionary history of these important zoonotic pathogens. African fruit bats including *Hypsignathus monstrosus* and *Epomops franqueti*, are the candidate natural reservoirs for filoviruses in the *Ebolavirus* genus; however, there have been no successful attempts to sequence or isolate *Ebolavirus sp.* from PCR-positive bats due to low viral copy numbers in the bats and difficulty associated with sampling from wild bat populations. We sought to increase the likelihood of acquiring live virus and viral whole genome sequences through extensive sampling from wild bat species in the Odzala-Kokoua National Park, Republic of Congo, within the geographical area of previous Zaire ebolavirus outbreaks. **Methods:** Multiple capture-release studies were performed to sample fruit bats over a period of four years. Bats were captured by mist netting near an *H. monstrosus* lekking tree and sampled for whole blood in addition to collecting nasal, urogenital, and rectal swabs. **Results:** In total, samples were taken from 456 *H. monstrosus* bats and 43 *E. franqueti* bats across four years of sampling. An additional 57 samples were taken from other bat species. Preliminary serological work shows 4.9% seroprevalence against Zaire ebolavirus in a subset of the *H. monstrosus* bats. **Conclusions:** The field collection efforts have yielded a large number of bats sampled which show a history of Zaire ebolavirus exposure. Future work will focus on detecting active infection with ebolavirus and isolation of live ebolavirus for whole genome sequencing.

24. **Co-infection in Georgian Bats**

Lela Urushadze[1,3], Ying Bai[2], Lynn Osikowicz[2], Ioseb Natradze[3], Ketevan Sidamonidze[1], Davit Putkaradze[1], and Michael Kosoy[2]

National Center for Disease Control and Public Health, Tbilisi, Georgia[1]; Centers for Disease Control and Prevention, Atlanta, USA[2]; Ilia State University, Tbilisi, Georgia[3]

Objectives: Bats have been recognized as natural reservoirs for a variety of zoonotic pathogens. The prevalence of different pathogens in bats could be associated with colony size and migration patterns. In this study, bats were collected from four different Georgian regions (Kakheti, Imereti-Tskhaltubo, Samegrelo, Kvemo Kartli) and were tested for different pathogens that are endemic to Georgia. **Methods**: In total, 218 bats (*Eptesicus serotinus*-20, *Miniopterus shrebersii*-27, *Myotis blythii*-67, *Myotis emarginatus*-38, *Pipistrellus pygmaeus*-12, *Rhinolopus Euriale*-26, and *Rhinolopus ferrumequinum*-22) were tested for four bacterial agents (*Bartonella, Brucella, Leptospira,* and *Yersinia*). Bat kidneys were dissected, and their DNA was tested for *Bartonella*, and *Leptospira*. Spleen DNA was tested for *Brucella* and *Yersinia*, and the intestine DNA was tested for *Yersinia*. Triplex Real-Time PCR (rtPCR) Assay was performed to detect *Brucella* (IS711), *Bartonella* (tmRNA), and *Yersinia* (pal). Singleplex rtPCR was used to identify *Leptospira* (LipL32). Targeting the 16S rRNA gene, conventional PCR was performed to detect multiple bacterial strains. Cultured *Bartonella* isolates of the *gltA* gene were sequenced. **Results:** A total of 113 (51%) were positive for at least one of the four pathogens. Co-infection was detected in different bat species from Tskhaltubo and Kakheti. One Tskhaltubo bat was positive for *Bartonella*, *Brucella*, and *Leptospira*. Two bats from Kakheti were co-infected with *Bartonella* and *Brucella*: (*Myotisblythii* (n=1), and *Miniopterusschreibersii* (n=1). Eighteen bats were co-infected with *Bartonella* and *Leptospira*: *Myotisblythii* (n=15), and *Miniopterusschreibersii* (n=3). Sequencing analysis confirmed a co-infection with two different *Bartonella* sequences from 16 different bats: *Myotisblythii blythii* (n=3), *Miniopterusschreibersii schreibersii* (n=7), *Myotisblythii emarginatus* (n=1), *Rhinolophus euryale* (n=2), and *Rhinolophus ferrumequinum* (n=3). All bats were negative for *Yersinia*. **Conclusions:** Our results indicate that bat colonies in Tskhaltubo have the highest prevalence of infection and co-infection; since these bats are in enclosed, small spaces such as caves, this may be a reason we see a mixture of pathogens and mutation. In the past couple of years', Georgian caves have become a popular tourist attraction; from a public health standpoint, it is important to know what types of pathogens exists in these local bats.

25. Caves of Myanmar: a high-risk human-wildlife interface for zoonotic disease
Megan E. Vodzak, MS, MPH[a], Ohnmar Aung, MBBS, MA [a], Marc T. Valitutto, VMD[a], Kyaw Y. N. Tun, BVSc, MSc, PhD [a], Heather S. Davies, MS [b], Michael E. von Fricken, PhD, MPH [a,b], Suzan Murray, DVM, DACZM[a], and Dawn M. Zimmerman, DVM, MS[a]

[a] *Global Health Program, Smithsonian Conservation Biology Institute, Washington, DC, USA*
[b] *Department of Global and Community Health, George Mason University, Fairfax, VA, USA*

The Southeast Asian country of Myanmar has been deemed a “hotspot,” both in terms of its biodiversity and disease emergence potential. Despite this recognition, there is a paucity of data and limited surveillance on emerging infectious diseases in Myanmar, due in part to almost five decades of political isolation. Recent changes in the government have expanded economic development, strengthening trade with neighboring countries and opening border access to tourists and investors, further contributing to potential underlying drivers of disease emergence. Of particular import and concern are zoonotic diseases arising from human-animal contact. The vast cave and karst system of Myanmar presents an understudied interface between humans and wildlife, such as bats, rodents, and non-human primates. Caves, particularly where intricate Buddhist shrines have been installed, are popular destinations for local, national, and international visitors despite high-contact potential with animals and their excrement. This poster underscores the growing risk of bat-borne pathogen exposure in relation to cave utilization in Myanmar, exemplified by the popular tourist destination town, Hpa-An.

26. **Prevalence Patterns of Coronaviruses in Lyle's flying fox (*Pteropus lylei*) in Thailand**
Supaporn Wacharapluesadee[1], Prateep Duengkae[2], Aingorn Chaiyes[2], Sangchai Yinsakmongkon[3], Pattarapol Maneeorn[4], Patcharakiti Phengsakul[2], Wachirapon Khumbucha[2], Thongchai Kaewpom[1], Apaporn Rodpan[1], Thiravat Hemachudha[1]

[1] World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University, [2]Faculty of Forestry, Kasetsart University, [3]Faculty of Veterinary Medicine, Kasetsart University,[4]Department of National Parks, Wildlife and Plant Conservation, Thailand.

Objectives Coronavirus (CoV) surveillance in Lyle’s flying fox (*Pteropus lylei*); a medium-sized flying fox which forms large colonies high up in trees in areas close to humans and other animals, was conducted to characterize strain of CoV and determine prevalence patterns in Chonburi province, Thailand. **Methods** *P. lylei* bats were captured monthly during January - December 2012 for detection of CoV at three closed areas in Chonburi province, two human dwellings which were 0.6 (S1) and 5.5 km (S2) away from the bat roost, and a bat roosting site (S3). Two nested RT-PCR of RNA-dependent RNA polymerase (RdRp) from rectal swabs were used for CoV detection. The strain of CoV was confirmed by sequencing and phylogenetic analysis. **Results** From 390 *P. lylei* bats, 239 were male and 151 were female, while 101 were juvenile (forearm length ≤136 mm) and 289 were adult. CoVs were detected in 68 bats, 17.4% using family-wide CoV PCR but not by group C betacoronavirus assay. The positive samples were found in eight months in the year that the study was conducted, the highest in June 2012. Ten mother–pup pairs were captured. Samples from 10 mothers were negative. Rectal swabs from 9 unweaned pups were available for CoV PCR assays and three of them were positive. PCR positive pup was identified with a PCR negative mother. Phylogenetic analysis of conserved RdRp gene revealed that the detected CoVs belonged to group D betacoronavirus (n=64) and alphacoronavirus (n=4). **Conclusions** Younger bats appeared to play a more significant epidemiological role in harbouring CoV. Young age but not sex or gravidity, correlated significantly with CoV detection. CoV was found in unweaned pups whose mothers tested negative for CoV. One possible conclusion is transient shedding from mother during peri-partum to the young, may maintain the virus transmission within the population. The immune status of young and adult bats against CoV, in terms of susceptibility to infection, needs to be studied to explore this. Further study into the association of CoVs with natural hosts is necessary to understand their prevalence and maintenance patterns, to evaluate its zoonotic potential.

27. Genetically Diverse Filoviruses in *Rousettus* and *Eonycteris* spp. Bats, China, 2009 and 2015

Email address:

Bats have been implicated as natural reservoirs for filoviruses based on serological or nucleotide evidence from 19 bat species in 8 countries across Asia, Africa, and Europe. Previously, we discovered filovirus antibodies in several bat species in China. Here we report genetically divergent novel filoviruses are circulating in the *Rousettus* and *Eonycteris* bats from China. The 310-bp L-gene sequences exhibited 65–99% nucleotide (nt) identity among themselves and 61–78% nt identity with known filoviruses. Phylogenetic analysis of these sequences suggests that at least 3 distinct groups of filovirus are circulating in these bats. Q-PCR results showed these filoviruses were mainly located in the lung, with genome copy number varying from 29 to 523,582/mg of tissue. Thus, these filoviruses may have the potential to be transmitted through the respiratory tract. Co-infection with four different filoviruses was found in a single bat. ELISA and Western Blot showed the antibodies reacting more strongly to EBOV NP than RESTV NP in some filovirus RNA negative bats. One of the viruses named BtFilo9447 were tried to amplify the whole genome. The GP gene of BtFilo9447 shared 34-39% similarity on aa level and 35-53% similarity on nt level with known filoviruses. Our results demonstrate that fruit bats may are important reservoirs of filoviruses. Considering their feeding habitats, fruit bats are often in close contact with domestic animals and human populations. It is therefore necessary to establish long-term and proactive surveillance of these viruses and related diseases.

28. **Development of a monoclonal antibody to Jamaican fruit bat CD3γ**
Miles Eckley, Ann Hawkinson, Tyler Sherman, Tony Schountz, Corey L Campbell

[1]Arthropod-borne and Infectious Diseases Laboratory, Colorado State University and [2]Department of Biology, University of Northern Colorado.

Objective: T cells have critical immunomodulatory roles in the innate immune response to infection. The CD3 cell-surface protein complex is required for T cell activation, and thus treating bats with therapeutic Aj-anti-CD3 IgG antibodies may have immunosuppressive effects. Monoclonal antibodies are of particular interest for this application because of their ability to bind to the Fc receptor of phagocytic and cytotoxic cells and label a pathogen for destruction. Our goal is to investigate the biological mechanisms by which T cells may induce immunopathology in response to viral infection. **Methods**: BALB/c mice were immunized and boosted with a KLH-conjugated 30mer peptide from Jamaican fruit bat CD3γ. Hybridoma cells were produced from the fusion of splenocytes with Sp2/0-Ag14 myeloma cells. Hybridoma cells were selected and cloned on methylcellulose plates, transferred to 24 well plates and supernatants screened. Candidates were identified by ELISA to 30mer peptide conjugated to BSA first, followed by flow cytometry of bat splenocytes. Antibodies were purified from supernatants by affinity chromatography using a protein A/G agarose resin bed. Isotype determination was done by ELISA using HRP labeled mouse anti-IgM, IgG2a, IgG1 and biotin labeled rat anti- IGg2b, IgA and IgG3 primary antibodies. **Results**: Three hybridoma clones for Aj-anti-CD3 IgG were purified from the cell culture supernatants and stored for later use. Each of the three hybridoma clones are expected to have produced a different isotype based on flow cytometry data. **Conclusions**: In future work, we will use Aj-anti-CD3 antibody labelling of T cells in vivo to deplete T cells and determine whether immunopathology to Tacaribe virus, which normally causes fatal infection, will be ameliorated.

29. **Bats and Immunity: Anti-Viral IFNγ Responses Differ Among Hosts**
C. Cotter, T. Schountz, C.L. Campbell

Arthropod-borne and Infectious Diseases Laboratory, Colorado State University

Anti-viral responses in bats (order Chiroptera) is largely unknown to researchers. Although bats account for 20% of all mammal species, they are relatively understudied in the scientific community (Baker et al., 2013). Bats are reservoir hosts for zoonotic diseases such as severe acute respiratory syndrome (SARs), rabies virus, and Ebola virus (Mandl et al., 2015). Reservoir hosts, generally, do not show pathogenic signs or succumb to disease when infected with such viruses. Current efforts by Kuzmin et al to better understand anti-viral responses in Egyptian rousette bat (*Rousettus aegyptiacus*) and human cells include a comparative study of host innate immune response to infection with Ebola virus or Marburg virus. They focused on the interferon (IFN) response. Kuzmin et al. demonstrated that bat IFNγ (type II IFN response) decreased viral replication in cell culture, whereas the human IFNγ produced by the human cells did not. Additionally, IFNγ stimulated the type I IFN (IFNα/β) response Kuzmin et al., 2017). My research focuses on Jamaican fruit bat (*Artibeus jamaicensis*—Aj) IFNg and its role in an anti-viral response to New World mammarenavirus Tacaribe (TCRV). *A. jamaicensis*, when infected with

TCRV, suffer fatal infections (Cogswell-Hawkinson, 2012). Most arenaviruses, TCRV excluded, produce a nuclear protein (NP) that blocks the type I IFN response at interferon response factor-3 (IRF-3) (Martinez-Sobrido et al., 2007). Pathogenesis of TCRV is still unknown; however I hypothesize that it interferes with the IFN response pathway by a different mechanism. Therefore, introduction of therapeutic Aj IFNγ to TCRV infected A. jamaicensis should be able to stimulate an appropriate, anti-viral innate immune response to rescue them from death. My project focuses on cloning, expressing, and purifying Aj IFNγ in order to synthesize a recombinant antibody for Aj IFNγ.

30. **Virome analysis of neotropical bats on the Caribbean island of Trinidad**

Janine F.R. Seetahal[1], Orchid M. Allicock[1,2], Stephen C. Sameroff[2], Christopher Oura[3], Vernie Ramkissoon[1], W. Ian Lipkin[2], Christine V.F. Carrington[1]

[1] Department of Preclinical Sciences, Faculty of Medical Sciences, The University of the West Indies, St Augustine, Trinidad and Tobago; [2] Center for Infection and Immunity, Mailman School of Public Health, Columbia University, New York, USA; [3] School of Veterinary Medicine, Faculty of Medical Sciences, The University of the West Indies, St. Augustine, Trinidad and Tobago

Objectives: Bats are recognized as reservoirs for a number of important zoonotic viruses. The Caribbean island of Trinidad is richly diverse in bat fauna with 68 species recognized. Viruses detected in Trinidad bats include Rabies virus, Tacaribe virus, Rio Bravo virus, Tamana bat virus and more recently a bat coronavirus. The objective of this study was to identify and characterize known and novel viruses in Trinidad bat species. **Methods:** During the period 2012- 2016, bats were sampled from 19 locations in Trinidad. The novel virome capture sequencing platform for vertebrate viruses (VirCapSeq-VERT) was employed to sequence faecal swab samples from 73 bats belonging to seven neotropical species (*Desmodus rotundus, Carollia perspicillita, Uroderma bilobatum, Molossus molossus, Molossus rufus, Pteronotus parnellii* and *Artibeus spp*). Sequence reads were processed using the bioinformatics pipeline at Center for Infection and Immunity to remove host background and assemble contigs that were then subjected to homology search using MegaBlast against the GenBank nucleotide database. Sequences that showed poor or no homology at the nucleotide level were searched against the GenBank viral protein database using BLASTx. The bat fecal samples were also screened by consensus PCR for 8 viral families (*Arenaviridae*, *Herpesviridae*, *Coronaviridae*, *Orthomyxoviridae*, *Alphaviridae*, *Flaviviridae*, *Rhabdoviridae*, *Picornaviridae*) using broadly reactive degenerate primers as outlined in the laboratory protocol for the PREDICT II surveillance project. All PCR products were confirmed by sequencing. **Results:** Consensus PCR detected sequences of Herpesviridae (bat herpesviruses) and Coronaviridae (bat coronaviruses). Preliminary analysis of VirCapSeq-VERT data provided evidence of both known and potentially novel viruses, the majority of which belonged to the families *Anelloviridae*, *Herpesviridae*, *Coronaviridae*, *Orthomyxoviridae*, *Parvoviridae*, *Rhabdoviridae* and *Retroviridae*. The *Anelloviridae* and *Herpesviridae* were detected primarily in fruit bats. The *Orthomyxoviridae* family included Influenza A viruses and were identified in *Desmodus* and *Molossus* species. *Parvoviridae* were overwhelmingly from *Desmodus* and *Artibeus* bats from one trapping site within the same year. *Rhaboviridae* viruses were detected in Desmodus bats sampled from various locations throughout the sampling period. The Retroviridae were primarily previously described bat endogenous retroviruses. **Conclusions:** Our results indicate the presence of a wide range of both known and novel viruses in faeces from Trinidad bats. The limited identification of viruses by consensus PCR as compared to the deep sequencing technique implies that viral detection is more efficient by targeted deep sequencing. Further analysis including targeted PCR and sequencing to assemble full genomes is required to further characterise the viruses detected. Analysis of other tissues will be required to distinguish between bat viral infections and viruses associated with animal prey.

31. **Delineating the phenotype and function of major lymphocyte populations in the fruit-eating bat, Pteropus Alecto.**

Periasamy P.[1,2], Martínez Gómez J.M.[1,2], Wang LF[3] , and Alonso S.[1,2]

[1]Department of Microbiology and Immunology, [2]Immunology Programme, Yong Loo Lin School of Medicine, Life Sciences Institute, National University of Singapore, Singapore. [3]DUKE-NUS, Singapore.

Objective: The unique ability of bats to act as reservoir for viruses that are highly pathogenic to humans suggests unique properties and functional characteristics of their immune system. However, the lack of bat specific reagents, in particular antibodies, has limited our knowledge of bat's immunity. **Methods and Results**: Here, using cross-reactive antibodies, we report the phenotypic and functional characterization of CD3+ T cell subsets, CD19+ B and NK1.1+ NK cells in the fruit-eating bat Pteropus alecto. Our findings indicate the predominance of CD8+ T cells in the spleen from wild-caught bats that may reflect either the presence of viruses in this organ or predominance of these cells at steady state. In addition, bone marrow of the bat contains over 30% T lymphocytes. This is significantly greater when compared to the T cell percentages in human and mouse bone marrow which ranges between 4% and 8%. Uniquely, a significant proportion of CD3+ T cells in bat spleen constitutively express IL-17A, IL-22 and TGF- at the mRNA level. Hence, the spleen may contain a substantial population of naïve T cells that are programmed to readily differentiate into TH17 cells or Tregs. Furthermore, mitogenic stimulation induced proliferation of bat immune cells and production of cytolytic molecules granzyme and perforin, and cytokines IL-2, IL-10, TNF and IFN. Additionally, we also demonstrate B cell function via calcium flux assay. **Conclusions**: This work paves the way towards a better understanding of bat's immunity that may offer new perspectives of therapeutic interventions for humans.

32. **Seasonal serological signals in viral infections for Madagascar fruit bats**

Cara E. Brook[1], Hafaliana C. Ranaivoson[2], Christopher C. Broder[3], Andrew A. Cunningham[4], Andrea L. Graham[1], Jean-Michel Héraud[2], Louise Wong[4], James L.N. Wood[5], Andrew P. Dobson[1*], C. Jessica E. Metcalf[1*]

[1]Department of Ecology and Evolutionary Biology, Princeton University; [2]Virology Unit, Institut Pasteur of Madagascar; [3]Department of Microbiology and Immunology, Uniformed Services University; [4]Institute of Zoology; Zoological Society of London; [5]Department of Veterinary Medicine; University of Cambridge;
*These senior authors contributed equally to this work.

Objectives: Considerable evidence supports a seasonal driver of bat-borne zoonoses, with most spillover events aligned with the synchronous reproductive season of the bat host in question. Previous modeling work proposes three possible mechanisms which could underpin such seasonality: classic Susceptible-Infectious-Recovered (SIR) dynamics with a seasonal influx of naïve juveniles, Susceptible-Infected-Recovered-Susceptible (SIRS) dynamics with periodic, waning immunity, and Susceptible-Infectious-Latent-Infectious (SILI) dynamics, by which hosts maintain virus persistently but shed seasonally. We fit variations on these contrasting dynamic models to age-seroprevalence data for henipavirus infections in Madagascar fruit bats in order to test these hypotheses. **Methods:** We live-captured, serum-sampled, and extracted lower premolar teeth (under anesthesia) from 340 Madagascan fruit bats (Eidolon dupreanum) over an eighteen-month seasonal trajectory. Serum samples were subjected to Luminex assay for henipavirus antibodies, and teeth underwent histological processing to quantify bat age, resulting in the construction of age-serprevalence curves for heniapivrus exposure in E. dupreanum. We fit variations on SI, SIR, SIS, and SIRS compartmental models to these data and used generalized additive models (GAMs) to investigate seasonal variation in antibody titers for both sexes, including several individuals recaptured across our time series. **Results:** Seroprevalence to henipavirus increased with age across the early years of life in our dataset, then declined to zero in later life. Field data were best fit by either frequency-dependent transmission models incorporating infection-induced mortality or by density-dependent transmission models, allowing for rapid waning of immunity. GAM analysis of seasonal trends showed significant seasonality in an animal's serostatus, corresponding to the nutritional calendar for male bats and the reproductive calendar for female bats. Recaptured individuals demonstrated considerable dynamism in antibody titers, changing serostatus in both directions across our time series. **Conclusions:** Our analyses suggest that henipavirus infections in E. dupreanum fruit bats are governed by highly dynamic transmission mechanisms, involving rapidly waning immunity and seasonal peaks and troughs in infection status. We reject a classic SIR model in favor of a more flexible SIRS or SILI model underpinning viral transmission among bat hosts in our system. More fine-scale field data will be needed to further parse remaining hypotheses.

Subject: Cancelation of the 3rd International Symposium on Infectious Diseases of Bats

Dear Colleagues,

As you may have expected, due to the COVID-19 outbreak, the*3rd International Symposium on Infectious Diseases of Bats* has been canceled. We are considering hosting the meeting in the summer of 2021 if the resources are available to do so. If so, I will send another email this fall altering you.

For those of you who have already paid your registration, you will receive a full refund from the Colorado State University Conference Services. I have been told this can take about a month, so if you have not received a refund by April 20, please email me and I will contact Conference Services.

Thank you for your understanding.

Tony

Dear Colleagues,

Registration is now open for the 3rd International Symposium on Infectious Diseases of Bats. With the emergence of yet another pathogenic coronavirus, we are planning to have an extended session to learn from one another about this new virus and I hope some of you can foster collaborative interactions while you are here. The URL for the meeting is:

http://www.batid.org

Please note a few important dates. **Abstract submission closes on April 17, 2020**. The format of the abstract is indicated on the web site and we ask that you follow it for purposes of continuity in the program. In addition, please send MS Word, Apple Pages or Rich Text files so that we can rapidly build the program. Please DO NOT send a PDF because they are much more difficult to integrate into the program. After you submit your abstract, you should receive a confirmation email. If you do not, please let me know and I'll resolve the issue.

Registration will close on May 1, 2020. Registration will be handled by the Colorado State University Conference Services with a direct link on the Bat ID web site. You can select registration only, or registration with dormitory housing on campus near the conference venue (Lory Student Center). Registration included breakfast for the two days, and the dormitory includes breakfast, too. If you prefer to stay in a hotel, the Fort Collins Hilton (on Prospect Avenue) and the Best Western University Inn are walking distance to campus. Links to these hotels are provided on the Registration page.

We also have the pleasure of hosting**This Week in Virology**. Vincent and crew will record an episode from the meeting.

Please let me know if you have questions or comments.

Thanks very much, and we are looking forward to seeing you again in Fort Collins.

Tony

Subject: Infectious Diseases of Bats Symposium, June 29-July 1, 2017, Fort Collins, Colorado

Dear Colleagues,

This email is the final reminder that the abstract submission deadline for the symposium is this **Friday, April 14**. The web page has been updated with the confirmed speaker list on the **Topics** page. After the abstract deadline, abstracts from those who requested talks will be evaluated by the selection committee for oral presentations. We plan to have the final selection for talks soon after and notifications sent by email. All abstracts submitted for posters will be accepted, provided they are relevant.

Early registration closes May 1 and late registration closes May 15.

http://www.batid.org

If you have any questions, please do not hesitate to contact me.

Thank you,

Tony Schountz

>
> Dear Colleagues,
>
> We have had several requests for an abstract submission deadline extension, thus, it has been extended two weeks to **Friday, April 14**. This is probably a fixed deadline because we will still need to select abstracts for talks, which will take a couple of weeks for the external reviewers to complete. If this is still not enough time for you, please let me know. We can add poster abstracts for a few weeks after this deadline, but after April 14 we will be unable to consider abstracts for oral presentations.

This email is to inform you that we have begun the process of setting up the symposium for next summer. Because we nearly exceeded the capacity of the conference hall in 2014, we have secured a larger room that can accommodate up to 300 attendees, and which has better viewing and acoustics for presentations.

Subject: Infectious Diseases of Bats Symposium; Presentations and Registration Deadline

Colleagues,

A list of oral and poster presentations is now available on the web site (http://www.batid.org) under the Topics tab. This list is provisional; however, we expect the times of the talks will be as listed. If you have questions or if we have made an error on your presentation please let me know. The final program will include all author affiliations and we expect to have it completed in two to three weeks.

Please also note that the registration deadline is Monday. We will keep registration open for two weeks thereafter; however, there will be an additional charge of $50 per registration.

Thanks and we look forward to seeing you in Fort Collins.

Subject: Monoclonal antibodies

Jon, I think a really important part of the grant will be to make monoclonal antibodies to various proteins (e.g., CD antigens, cytokines) and cytokines as reagents. If you agree, I'd like to approach a colleague of my, Brian Geiss, to see if he is willing to be on the grant. Recombinant protein expression is his "thing" and he would be a great asset for the grant.

I also think we should get as many letters of support that we can get. I can probably get at least 10 from people we've helped over the years (provided tissues and cells, conducted experimental infections, etc.).

Let me know what you think.

Just moved into our new building. It is really sweet. :)

Thanks,

T.

Subject: NSF bat immunology interest

Hi everyone,

I hope you are all safe.

I wanted to let you know about two NSF programs that have urgent deadlines (first week of May) that has bat immunology as its principal interest. The first is a RAPID for 12 months/$200k (including direct costs) and EAGER for 2 years/$300k (including direct costs). The NSF contact is Dr. Joanna Shisler My understanding is they are interested in the biology of bat immune systems relevant to coronaviruses, but because of the potential spill back issues they will also consider nonviral diseases, including white nose syndrome. I don't have other information but I'm sure Dr. Shisler will be happy to chat with you if you are interested.

If you know of others who are interested in the biology of bat immunity, please pass this email along to them.

Thanks,

Tony

Tony, just an FYI, this overlaps (at the tail end) with the World One Health Congresshttps://onehealthplatform.com/wohc/home. May not be a big deal for most, but I think some of us were going to do the other meeting also. I haven't figured out my travel yet, but nonetheless I'll plan to come to CO so long as I can and really looking forward to this!

Dear Ben,

Your abstract submission has been accepted for a **POSTER** presentation. The session is **Friday, April 30 from 12:00 to 2:00 PM** in the University Center for the Arts. The maximum size of your poster **should not exceed 122 cm/48 inches height and width**. We will provide push pins for mounting your poster on the easel. If you have questions, please feel free to contact me.

Thank you and we look forward to your presentation.

Dear Zhengli,

If there is anything I can do to help you with your travels, please let me know. I can prepare a letter of invitation for you if you need it.

Peng, I'm sorry you cannot make it. I was looking forward to visiting with you about bat immunology. We have tried many ways of making bone marrow dendritic cells and macrophages but with little success. We have tried adapting mouse protocols with artibeus bat cytokine orthologs but the do not work as well with the bats as they do with mice. I am beginning to think the developmental pathways of bats and mice are substantially different.

I am sure all of you are overwhelmed with the coronavirus outbreak. I really hope it subsides soon because it has been really terrible for China.

Be safe.

Subject: Bat ID conference

Dear Zhengli and Peng,

I was wondering if you will be attending the bat meeting after ASV. (I realize some of you may be at the Paris meeting instead.) If so, I'd like to list you as confirmed speakers. I'm awaiting a small grant decision from my university that would be used to waive your registration fee if you are a confirmed speaker. The decision is supposed to be made in the next week or two, so I won't be able to let you know for sure until then. I understand you are quite busy with the new coronavirus and that there may be travel issues, but if it is possible for you to make it, I would be most grateful.

Thank you,

Tony

Right, Edinburgh. Somehow, I had in my mind it was the EEID meeting in Paris.

We will be sorry to miss your group here, it's always brought good science and information to the symposium.

Let me know if things change and we'll get you in.

Thanks,

Tony

Hi Jon

The Hilton on Prospect is only half a mile from the meeting. Theres also the University Inn Best Western on College Ave that is about a quarter of a mile.

See you in a couple of weeks.

Tony

Subject: Re: Bat MERS-CoV sera for S protein luminex-based assay R&D

Hi Kevin,

How much serum (volume) do you need? We have just finished an infection experiment with our Aj bats but we have not done the serology, yet.

Tony

On Dec 4, 2018, at 12:25 PM, Kevin Olival ecohealthalliance.org> wrote:

Dear Tony and Vincent,

Hope this finds you both well! I know Vincent is in the Congo, so his responses are delayed.

I'm working on a grant proposal (GHERI) with Chris Border and Eric Laing to do some serological screening and assay development for MERS-CoV and other CoVs using a Luminex-based platform. This builds off the work Broder and crew have already done, but will provide support for additional R&D for the MERS-CoV Spike assay, and for in-country capacity building and testing. The idea is to then use the multiplex CoV assays to screen bat sera that we are currently collecting under a DTRA supported project across Western Asia/Middle East (which I'm PI on, and Vincent is involved with).

In order to validate the MERS-CoV assay during the R&D phase,**it would be super helpful to have some confirmed MERS-CoV positive bat sera to work with**. Given that you guys have run MERS-CoV bat infection trials (and may be doing more?), I'm wondering what the possibility of getting some positive bat sera over to Chris' lab for validation? Also, in reading your paper again I remembered that you observed limited seroconversion in bats at 28 dpi… so maybe this is a moot question? Any additional evidence that supports seroconversion in bats?

The grant is due in a couple of weeks, so at this stage I'm just really looking for a general response if you think this is feasible, so we can throw a line in the proposal. i.e. "In collaboration with Vincent Munster (NIH) and Tony Schountz (CSU) we will validate our MERS S protein assay using positive control bat sera from previous experimental infection studies".

Please let me know your thoughts or any additional ideas.

Cheers,
Kevin

Dear Pat and Eun Chung,
It was wonderful to see you in Ft. Collins. I'm grateful that we had time to talk about this project and for your interest and support. Attached are two briefs which detail the scope of work and scientific rationale for setting up the Pteropus colony. Let's use this as a starting point for further discussion about a potential contract. I'd be happy to provide additional information as per your guidance.

Cheers,
Jon

Dear Colleagues,

As you may have expected, due to the COVID-19 outbreak, the*3rd International Symposium on Infectious Diseases of Bats* has been canceled. We are considering hosting the meeting in the summer of 2021 if the resources are available to do so. If so, I will send another email this fall altering you.

For those of you who have already paid your registration, you will receive a full refund from the Colorado State University Conference Services. I have been told this can take about a month, so if you have not received a refund by April 20, please email me and I will contact Conference Services.

Thank you for your understanding.

On Feb 19, 2020, at 4:09 PM, Schountz,Tony wrote:

Dear Colleagues,

Registration is now open for the 3rd International Symposium on Infectious Diseases of Bats. With the emergence of yet another pathogenic coronavirus, we are planning to have an extended session to learn from one another about this new virus and I hope some of you can foster collaborative interactions while you are here. The URL for the meeting is:

http://www.batid.org

Please note a few important dates. **Abstract submission closes on April 17, 2020**. The format of the abstract is indicated on the web site and we ask that you follow it for purposes of continuity in the program. In addition, please send MS Word, Apple Pages or Rich Text files so that we can rapidly build the program. Please DO NOT send a PDF because they are much more difficult to integrate into the program. After you submit your abstract, you should receive a confirmation email. If you do not, please let me know and I'll resolve the issue.

Registration will close on May 1, 2020. Registration will be handled by the Colorado State University Conference Services with a direct link on the Bat ID web site. You can select registration only, or registration with dormitory housing on campus near the conference venue (Lory Student Center). Registration included breakfast for the two days, and the dormitory includes breakfast, too. If you prefer to stay in a hotel, the Fort Collins Hilton (on Prospect Avenue) and the Best Western University Inn are walking distance to campus. Links to these hotels are provided on the Registration page.

We also have the pleasure of hosting**This Week in Virology**. Vincent and crew will record an episode from the meeting.

Please let me know if you have questions or comments.

Thanks very much, and we are looking forward to seeing you again in Fort Collins.

Hi Mattina,

I'm not sure who all needs to be on this reply so I cc'd everyone.

We can get these tissues for you from Jamaican fruit bats in our colony; however, they will have to be collected opportunistically. It may not be until January before we could collect them for you.

Regards,

Tony

As for gaining field experience within the next year I think I am limited to North America purely to minimize cost of gaining a foundation of skills/training...but for research questions I am able to develop and field studies I may want to propose for funding, a wider (global) range of locations can certainly be relevant and beneficial!
> >
> > For all that are curious or may be interested, here's a nutshell explanation of what my science interests are:
> >
> > Right now I'd like to characterize the localization and expression of gonadotropin inhibitory hormone (GnIH) in bats; it's a neuropeptide that inhibits the downstream signals involved in the hypothalamic-pituitary-gonadal

axis in vertebrates, but has yet to be described in any bat species. This fits into my broad interest of how environmental and social cues modulate reproductive physiology at a molecular level. For this basic early work, I'm looking to find people who are willing to donate existing, or collect, some tissue samples for me to work on in the lab (IHC, qPCR, westerns...). I'm looking for brains and gonads from any species of bat (male and female) either isolated and flash frozen, or fixed in formaldehyde of some kind. If any of you have insight into this that'd be awesome!

After this initial step, I'd also like to do my own field studies (shooting for 2018-2019) to wild-catch some bats across seasons within a region where species exhibit hibernation or torpor, and examine how GnIH and GnRH fluctuate seasonally across reproductive life history stages and suppression. This connects to ideas within the context of energy partitioning and tradeoff, within which I think those of you working in disease dynamics and immunology could be cool collaborators if interested. If I am able to terminally collect samples for myself perhaps others can collect data on immune aspects of the individuals across seasons as well. Just some early thoughts.

Looking forward to any feedback, potential field work training I can get, and maybe even ideas about where I can get tissues to start.

Mattina

I'm working under the supervision of Dr. George Bentley, developing projects that broadly encompass the ways animals translate environmental cues via neuroendocrinology to support (or inhibit) reproductive physiology. I have a few different project ideas surrounding bat reproductive neuroendocrine regulation that I'd be happy to chat about if anyone is interested, but I'm reaching out to this group to also offer my help, and ask for some help.
>
> - **I'm really interested in gaining some bat field experience and training in wild-capture (handling, mist netting, harp traps, etc.)** as this is something I'd like to do as part of my dissertation but have no experience. If you are planning to do field work of any capacity over the upcoming Spring/Summer and

would like a responsible set of eyes and hands to help, please let me know!

- I'm attempting to get some preliminary data this year regarding localization and expression of a neurohormone that inhibits the HPG axis in vertebrates. I'd like to characterize it in bats as a starting point and build funding proposals off of that for future field studies. This is where I need help - I am hoping to get some donated **brain, ovary, and testes** tissues from a few different bat species for me to do some IHC/gene expression work on. **If anyone has bat tissues of this type that they do not need for their own research programs, I'd love to talk further!** Flash frozen is ideal, and RNAlater or PFA fixed is also okay.

Thanks so much!

Jon, good news, Alan wants to move forward on this. He's willing to pony up the renovation funds, but he wants a one-page description for why it will be beneficial for the long-term. I suspect you have something already that could be edited? If so, send it to me and I'll get it to him.

Thanks,

T.

Hi Ben

Do I need to schedule a ride to the airport tomorrow? Also do you know if I can print my boarding passes here at the hotel?

Thanks

Tony

Yes Dr.Schountz.

The pick-up from the airport to the hotel will be arranged.

Safe journey and see you soon.

Best

Ben

Jon, I am really, really, terribly sorry I missed your email. I only found it because I was going through the replies to locate an errant email and yours was in the midst of them.

I think if you can do it with a focus on the bat viruses that would be great. Just to let you know, we are also hosting the INKY meeting this year, where other viruses would be relevant.

http://www.zonnosis.org

Still a work in progress, though.

The bats are doing well since the move from Greeley to FC. It took 2 years get through all the hoops to move them here. Anyway, we've done a few more infection experiments and have one more virus that kills them. We need the colony to expand quite a bit, so we're sort of pausing on infection studies for a few months.

Tony

Dear Colleagues,

We have had several requests for an abstract submission deadline extension, thus, it has been extended two weeks to **Friday, April 14**. This is probably a fixed deadline because we will still need to select abstracts for talks, which will take a couple of weeks for the external reviewers to complete. If this is still not enough time for you, please let me know. We can add poster abstracts for a few weeks after this deadline, but after April 14 we will be unable to consider abstracts for oral presentations.

Please let me know if you have any question.

Thanks,

Tony

Colleagues,

Please note that abstract submission for the symposium is now closed. We received 66 abstracts (compared to about 45 for the first meeting). For those of you who requested oral presentations, the abstracts will go to the members of the selection committee tomorrow and you will be notified next week if yours was selected for a talk or a poster. We will do our best to accommodate as many speakers as possible.

As a reminder, symposium registration closes in about 2 weeks, on**May 1, 2017**.

If you have questions, please feel free to contact me.

Thank you,

Tony

The web page has been updated with the confirmed speaker list on the **Topics** page. After the abstract deadline, abstracts from those who requested talks will be evaluated by the selection committee for oral presentations. We plan to have the final selection for talks soon after and notifications sent by email. All abstracts submitted for posters will be accepted, provided they are relevant.

Hi Ben,

I'm having trouble getting my visa for my visit. Apparently, I need the letter from you that has some kind of seal stamped on it, and this letter requires my passport number is listed on it. That number is 546272602. My legal name is **William A Schountz** and this is the name on my passport so the letter should be addressed with that name. Can you mail the letter directly to me at:

William Schountz

It would be helpful to get the letter by the end of next week because I need my passport back by September 14 for upcoming travel. I cannot get the passport back until I have the visa approved.

Thanks,

Tony

主题: Re: Invitation to the 8th International Symposium on Emerging Viral Diseases

Hi Ben,

I have my flight booked and will arrive in Wuhan at 10:00 PM on October 19 (All Nippon Airways NH 937). Can you tell me the name and address of the hotel? I will need it for my visa and for my university administrators.

Thank you,

Tony

Dear Dr.Schountz:

The 8th International Symposium on Emerging Viral Diseases will be held in October 20-22, 2018, in Wuhan, China. The biennial symposium is organized by Wuhan Institute of Virology, Chinese Academy of Sciences and has become an important event for leading Chinese and international virologists to discuss cutting-edge science on emerging viruses as well as to foster global collaborations.

Prof Zhengli Shi and Dr.Peng Zhou had a nice experience last year in Colorado when attending the symposium on bat-borne infectious diseases, and we know you have made great contributions to bat virus researches. We sincerely hope that you can attend the symposium. Please find enthe formal invitation letter for the meeting.

If you have any question regarding the conference, please contact me.

Thank you!

Best regards

Ben Hu Ph.D

Research Assistant

Secretary of the 8th International Symposium on Emerging Viral Diseases

Wuhan Institute of Virology, Chinese Academy of Sciences
Wuhan 430071, P.R. China

Hi Ben,

Attached is my abstract. I should have quite a bit more information for the talk as we have many bats infected with the virus and are getting some very interesting results.

Thanks,
Tony

Infection and Immune Responses of Jamaican Fruit Bats (*Artibeus jamaicensis*) Experimentally Challenged with a Bat HL18NL11 Influenza A Virus

Tony Schountz, PhD

Arthropod-borne and Infectious Diseases Laboratory, Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University

Nucleotide sequences of two novel influenza A-like viruses, HL17NL10 and HL18NL11, were recently discovered in New World little yellow shouldered fruit bats (*Sturnira lilium*) and flat-faced fruit bats (*Artibeus planirostris*), respectively. Serological studies indicated high prevalence to these viruses among many species of Phyllostomidae leaf-nosed fruit bats of Central and South America, including Jamaican fruit bats (*Artibeus jamaicensis*). Infectious viruses have not been isolated from bats, therefore an infectious clone of HL18NL11 was generated by reverse genetics technologies and inoculated into Jamaican fruit bats. During a 28 day challenge experiment with intranasal inoculation, the bats exhibited no clinical signs of disease. However, rectal swabs had up to 10^5 $TCID_{50}$ equivalents of HL18NL11 vRNA by real-time PCR in each bat on days 2, 4 and 7 post inoculation, and in the lungs of one of the bats on day 28 when they were euthanized. Inclusion of contact bats two days after inoculation resulted in virus transmission. Histopathology revealed minimal evidence of disease except for the one bat with detectable vRNA in its lung. This bat's lungs had aggregates of macrophages and lymphoplasmacytes intermixed with fewer neutrophils that expanded into the interstitium, especially around the adventitia. RNAscope probes identified vRNA in the jejunal Peyer's patch of acutely-infected bats and nuclear localization of viral antigen. Bats held to 28 day each had low titer neutralizing antibodies. In a second study, inoculation of bats with a mutant HL18NL11 virus with a premature stop codon in the neuraminidase replicated poorly; however, the virus transmitted to contact bats and with each bat passage resulted in greater abundance of vRNA in rectal swabs, suggesting the virus may have reverted back to wildtype. This work is the first in vivo study of bat influenza viruses and supports the hypothesis that Jamaican fruit bats may be a natural reservoir host of the HL18NL11 virus.

No, just the title for now. I'll need an abstract in a few weeks for the program. I already have you listed on the web site with your title.

I've received quite a few abstracts - more than the last time, it seems, so I think it will shape up to be another good meeting.

Thanks,

T.

Awesome - and agree.
I would like to brainstorm together for the letters before we approach anyone. I'll start a google doc and we can live edit it.
Let's think about who the 'dream team' will be for this.
It also occurred to me - what do you think about building in a facility in Bangladesh where we keep a captive breeding colony, that would serve as a feeder if we need more bats along the way? We could develop and fund a closed colony there, like what Cambridge did in Ghana, and we'd know the status of each bat. Brian Pope would be great at helping set this up. And it would allow the colony at CSU to fluctuate a bit in size, and we could pull in new bats as needed. I think it's a nice insurance policy to support the colony in CO as we develop it. This could be something I would manage - but I think we could convince the govt and if we provide all the funding for construction and upkeep, it could really happen.

Thoughts?

Thanks so much Brian.
It sounds like the space might be too small for the size colony we were thinking of founding (as you noted, Greg). We should discuss whether a smaller founder colony might still make sense given the opportunity we have. I think the consideration is whether the colony could produce a sufficient birth cohort each year to allow for meaningful research. For example, if we reduced the planned size from 40 to 20, with 3 males and 17 females, with 15 expected to produce pups each year, we'd have 35 bats in Y1 - still within capacity. And we could plan to use most if not all of F1. Long term, we would just have to manage the colony to keep it within size. We could selectively breed a subgroup of females in alternate years, as well.

Just brainstorming here. Tony and Greg, please weigh in. Meanwhile, I'm also going to speak with Jean to push back on the need for construction money to build a bigger facility.

Cheers,
Jon

Cc: Ebel,Greg >; Tony Schountz
Subject: Pteropus space requirements

Hi Brian,

I wanted to introduce you to Professor Greg Ebel, who's the Director of the Arthropod-Borne and Infectious Disease Lab at Colorado State and who's recently become a partner in our efforts, with Tony Shountz, to establish a Pteropus breeding colony there. We're trying to get an accurate understanding of the physical space required for the proposed colony, which if you recall we had discussed starting with 40 bats (4 male, 36 female) which would then become about 60-70 bats post breeding.

Could you help give us a sense of what physical space you think would be necessary in terms of a holding / flight cage, plus support rooms like food storage and a handling / exam area? We've got an existing building on campus that's abou 2500 sq ft that could be gutted & equipped as needed, but the concern is that it's just not big enough for the planned number of bats.

Thanks for your help in thinking through this.

Cheers,

Jon

> Hi Jon,
>
> It's been awhile since we've spoken but I hope you are doing well. Jean forwarded me your question about hypothesis-driven research in an R24. In general, I think we should probably schedule a brief call to discuss

some of the specifics of R24s but also to hear about what you're thinking in terms of a hypothesis-driven approach (or aim). I've listed below some times that work for me/Jean/Mark, please let me know if any of those would work for your team as well.

October 5th: 9-9:30a (eastern)

October 7th: 3-3:30pm

October 14th: 10-11am, 1-2pm, or 2:30-3:30p

October 15th: 11a-noon or 3-4pm

In the interim though, here are some additional thoughts:

The R24 FOA indicates that this mechanism should be used to develop, maintain, provide a resource, but it doesn't explicitly state that hypothesis-driven research is not allowed. Our branch currently has one other funded R24 for the World Reference Collection of Emerging Viruses and Arboviruses (WRCEVA) at UTMB. This R24 does include hypothesis-driven research; they conduct small research projects that leverages having full access to the collection and to samples gathered through pursuit of adding new items to the collection. This research is usually a discreet, small project so as not to take up a lot of the budget and makes use of the resource to answer significant research questions that others haven't addressed yet and that may be difficult to work into other separate applications. I will have to search for other R24s across the institute that may have included animal model development as part of their aims, but none are coming to mind at the moment that would serve as a good example.

Sincerely, Sara

Sara E. Woodson, PhD

Program Officer

On Oct 7, 2020, at 1:51 PM, Woodson, Sara (NIH/NIAID) [E] > wrote:

Hi Tony, Jon, and Greg;
Here are the example R24's you may want to look up in NIH Reporter:

R24AI059830 PI: Jacques Robert (University of Rochester, animal model containing)
R24AI120942 PI: Scott Weaver (University of Texas Medical Branch, WRCEVA—no model development but may be relevant if thinking about including training; may also be good to link in with them for potential distribution of critical reagents along with BEI Resources)

As Mark mentioned on the phone, NIAID doesn't allow a lot of R24 grants and thus not many are funded, so there aren't many relevant examples to what you would be putting forth in your R24. Please let me know if you have other questions or concerns!
Happy writing 😊
Sincerely, Sara

Attachment(s): "jmv.25817.pdf"

Jon, attached is the paper with the ACE2 sequences that led us down the deer mouse path for SARS2 susceptibility. I've highlighted the 7 Rhinolophus species on page 2 as well as the table with the 20 critical amino acids. (Deer mice have 17 of these 20.) So, R. pearsonii is the closest, but I suspect there may be other Rhinolophus species that have not had ACE2 sequences determined that may be closer to the 20 found in humans, and which may be more likely to be susceptible. It would be helpful if we could get as many ACE2 sequences as possible but we'd need access to lung RNA from each of them to do the PCR and sequencing. I'm suspect someone at Wuhan or elsewhere in China are already doing this. Identifying which facilitate virus entry (e.g., transfection experiments) would point to the best candidates for susceptibility and which we would want to import for one-off susceptibility experiments.

Abstract

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) causes the recent COVID-19 public health crisis. Bat is the widely believed original host of SARS-CoV-2. However, its intermediate host before transmitting to humans is not clear. Some studies proposed pangolin, snake, or turtle as the intermediate hosts. Angiotensin-converting enzyme 2 (ACE2) is the receptor for SARS-CoV-2, which determines the potential host range for SARS-CoV-2. On the basis of structural information of the complex of human ACE2 and SARS-CoV-2 receptor-binding domain (RBD), we analyzed the affinity to S protein of the 20 key residues in ACE2 from mammal, bird, turtle, and snake. Several ACE2 proteins from *Primates*, *Bovidae*, *Cricetidae*, and *Cetacea* maintained the majority of key residues in ACE2 for associating with SARS-CoV-2 RBD. The simulated structures indicated that ACE2 proteins from *Bovidae* and *Cricetidae* were able to associate with SARS-CoV-2 RBD. We found that nearly half of the key residues in turtle, snake, and bird were changed. The simulated structures showed several key contacts with SARS-CoV-2 RBD in turtle and snake ACE2 were abolished. This study demonstrated that neither snake nor turtle was the intermediate hosts for SARS-CoV-2, which further reinforced the concept that the reptiles are resistant against infection of coronavirus. This study suggested that *Bovidae* and *Cricetidae* should be included in the screening of intermediate hosts for SARS-CoV-2.

KEYWORDS

ACE2, *Bovidae*, *Cricetidae*, intermediate host, SARS-CoV-2

1 | INTRODUCTION

Coronavirus disease 2019 (COVID-19), which was first reported in Wuhan, Hubei province, China, has caused over 80 422 human infections and more than 2984 deaths (as of 4 March 2020) in China.[1,2] The confirmed cases outside China are increasing, which raised major global concern. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was identified to be the pathogen of COVID-19. SARS-CoV-2 has joined SARS-CoV and Middle East respiratory syndrome-related coronavirus (MERS-CoV) as another coronavirus that causes severe respiratory disease and human death.[3,4]

The specificity of the interaction between virus and receptor determines its host range for the virus. Spike protein (S) of SARS-CoV-2 has attracted great attention because of its role in receptor binding. Angiotensin-converting enzyme 2 (ACE2) binds to the receptor-binding domain (RBD) of SARS-CoV-2 S protein and functions as a receptor for SARS-CoV-2.[5,6] The origin of SARS-CoV-2 is considered as bat.[6] However, the intermediate host is unknown. Some studies suggest that pangolin is involved in the evolution of SARS-CoV-2.[7,8] Others suggested that snake and turtles are potential intermediate hosts for SARS-CoV-2.[9,10] In this study, we compared the key amino acids (AAs) in ACE2 from different species for the binding ability to RBD. On the basis of

potential interaction between S protein and ACE2, it was speculated that SARS-CoV-2 preserved the ability to infect *Bovidae* and *Cricetidae* but not snake or turtle.

2 | METHODS

2.1 | Sequence analysis of ACE2

A total of 93 ACE2 protein sequences were selected from 85 mammals, 4 birds, 3 turtles, and 1 snake. These ACEs with their corresponding species are listed as follows: hACE2: *Homo sapiens* (BAB40370.1), RhiACE2: *Rhinopithecus roxellana* (XP_010364367.2), MacmACE2: *Macaca mulatta* (NP_001129168.1), MuseACE2: *Mustela erminea* (XP_032187679.1), CamdACE2: *Camelus dromedarius* (XP_031301717.1), PlACE2: *Procyon lotor* (XP_031301717.1), PcACE2: *Paguma larvata* (AAX63775.1), RmACE2: *Rhinolophus macrotis* (ADN93471.1), RfACE2: *Rhinolophus ferrumequinum* (BAH02663.1), RsACE2: *Rhinolophus sinicus* (ADN93472.1), RlACE2: *Rousettus leschenaultii* (BAF50705.1), SsACE2: *Sus scrofa* (NP_001116542.1), MpfACE2: *Mustela putorius furo* (BAE53380.1), RatACE2: *Rattus norvegicus* (Q5EGZ1), MmACE2: *Mus musculus* (Q3URC9), ClfACE2: *Canis lupus familiaris* (J9P7Y2), FcACE2: *Felis catus* (A0A384DV19), MjACE2: *Manis javanica* (XP_017505752.1), RpACE2: *Rhinolophus pearsonii* (ABU54053.1), PvACE2: *Pteropus vampyrus* (XP_011361275.1), PoaACE2: *Pongo abelii* (NP_001124604.1), EcACE2: *Equus caballus* (F6V9L3), BtACE2: *Bos taurus* (Q58DD0), PtACE2: *Pan troglodytes* (A0A2J8KU96), OraACE2: *Ornithorhynchus anatinus* (F7FDA2), OvaACE2: *Ovis aries* (W5PSB6), PanACE2: *Papio Anubis* (A0A096N4X9), LaACE2: *Loxodonta africana* (G3T6Q2), SsdACE2: *Sus scrofa domesticus* (A0A220QT48), EeACE2: *Erinaceus europaeus* (A0A1S3APE5), OcACE2: *Oryctolagus cuniculus* (G1TEF4), NpACE2: *Nyctereutes procyonoides* (B4XEP4), VvACE2: *Vulpes vulpes* (A0A3Q7-RAT9), PhcACE2: *Phodopus campbelli* (C7ECU7), MaACE2: *Mesocricetus auratus* (C7ECV1), CjACE2: *Callithrix jacchus* (F7CNJ6), SusACE2: *Suricata suricatta* (XP_029786256.1), HgACE2: *Heterocephalus glaber* (A0A0N8EUX7), DoACE2: *Dipodomys ordii* (A0A1S3GHT7), ItACE2: *Ictidomys tridecemlineatus* (XP_005316051.3), CpACE2: *Cavia porcellus* (XP_023417808.1), CgACE2: *Cricetulus griseus* (A0A061HZ66), ChACE2: *Capra hircus*(A0A452EVJ5); BibtACE2: *Bos indicus x Bos taurus* (A0A4W2H3A1), BmACE2: *Bos mutus* (L8I4I4), NlACE2: *Nomascus leucogenys* (G1RE79); CsACE2: *Chlorocebus sabaeus* (A0A0D9RQZ0); MfACE2: *Macaca fascicularis* (A0A2K5X283); PpACE2: *Pan paniscus* (A0A2R9BKD8); CaACE2: *Cercocebus atys* (A0A2K5KSD8); MnACE2: *Macaca nemestrina* (A0A2K6D1N8); MalACE2: *Mandrillus leucophaeus* (A0A2K5ZV99); TsACE2: *Tarsius syrichta* (A0A1U7TY97); PrcACE2: *Propithecus coquereli* (A0A2K6GHW5); UmACE2: *Ursus maritimus* (A0A452TT30); OgACE2: *Otolemur garnettii* (H0WMI5); SbbACE2: *Saimiri boliviensis boliviensis* (A0A2K6SBD4); CciACE2: *Cebus capucinus imitator* (A0A2K5PYM0); GggACE2: *Gorilla gorillagorilla* (G3QWX4); AnACE2: *Aotus nancymaae* (A0A2K5DQI6); ChaACE2: *Chlorocebus aethiops* (Q1LZX8); AmACE2: *Ailuropoda melanoleuca* (G1MC42); VuACE2: *Vombatus ursinus* (A0A4X2M679); UaACE2: *Ursus americanus* (A0A452R1Z9); UahACE2: *Ursusarctos horribilis* (A0A3Q7TE16); PmACE2: *Physeter macrocephalus* (A0A2Y9S5T9); LvACE2: *Lipotes vexillifer* (A0A340Y3Y6); BasACE2: *Balaenoptera acutorostrata scammoni* (A0A452CBT6); DlACE2: *Delphinapterus leucas* (A0A2Y9M9H3); TtACE2: *Tursiops truncatus* (A0A2U4AJL3); NaaACE2: *Neophocaena asiaeorientalis asiaeorientalis* (A0A341BCI8); CuACE2: *Callorhinus ursinus* (A0A3Q7N3M7); NsACE2: *Neomonachus schauinslandi* (A0A2Y9GEI9); TmlACE2: *Trichechus manatuslatirostris* (A0A2Y9E393); EllkACE2: *Enhydra lutriskenyoni* (A0A2Y9KLV0); ClACE2: *Chinchilla lanigera* (C7ECU0); MdACE2: *Monodelphis domestica* (F6WXR7); LpACE2: *Lynx pardinus* (A0A485NF12); PaACE2: *Pipistrellus abramus* (C7ECT9); MbACE2: *Myotis brandtii* (S7N573); DrACE2: *Desmodus rotundus* (K9INV8); RhpACE2: *Rhinolophus pusillus* (E2DHI9); RaACE2: *Rhinolophus alcyone* (A0A0N7IQX6); RlACE2(2): *Rhinolophus landeri* (A0A0P0IB69); MylACE2: *Myotis lucifugus* (G1PXH7), GgACE2: *Gallus gallus* (F1NHR4), ApACE2: *Anas platyrhynchos* (R0LHX5), MgACE2: *Meleagris gallopavo* (G1NPB8), CaaACE2: *Cathartes aura* (A0A091MDI4), OhACE2: *Ophiophagus hannah* (V8NIH2), CpbACE2: *Chrysemys picta bellii* (XP_023964517.1), CmACE2: *Chelonia mydas* (XP_007070561.1); and PsACE2: *Pelodiscus sinensis* (XP_006122891.1). On the basis of known 20 key sites in human ACE2 interacting with SARS-CoV-2 RBD,[11] we analyzed whether these sites were conserved on other ACE2 proteins. Phylogenetic and molecular evolutionary analysis of ACE2 protein was conducted using molecular evolutionary genetics analysis version X (MEGA-X).[12] Phylogenetic tree was generated with Jones-Taylor-Thornton evolutionary model using a maximum-likelihood method.

2.2 | Structure simulation of ACE2-RBD complex

On the basis of the structure of hACE2 with SARS-CoV-2 S RBD (PDB: 6LZG), the structure of SARS-CoV-2 S and ACE2 from *Bos taurus*, *Cricetulus griseus*, *Pelodiscus sinensis*, and *Ophiophagus hannah* were simulated by SWISS-MODEL online server[13] and analyzed by Chimera software version 1.14.[14]

3 | RESULTS

3.1 | Sequence alignment of ACE2

According to the recently resolved structure of the complex of human ACE2 and SARS-CoV-2 RBD, there are 20 key AAs in hACE2 for interacting with RBM.[11] We analyzed those AAs of ACE2 protein from a list of mammals, birds, turtles, and snake, as shown in Table 1. Next, a phylogenetic tree for mammalian ACE2 proteins was constructed by MEGA-X software. There were 16 *primates* ACE2, 5 *Bovidae* ACE2, 2 *Cricetidae* ACE2, and 3 *Cetacea* ACE2 (Table 1 and Figure 1A), possessing at least 90% (18/20) critical AAs. Pangolin ACE2 preserved only 70% (14/20) AAs. Nearly half of the key residues in turtles (CpbACE2, CmACE2, and PsACE2) and snake (OhACE2) were changed (Table 1). ACE2 from *Aves*, including *Gallus gallus*, *Anas platyrhynchos*, *Meleagris gallopavo*, and *Cathartes aura*, only matched 10 to 11 AAs (Table 1).

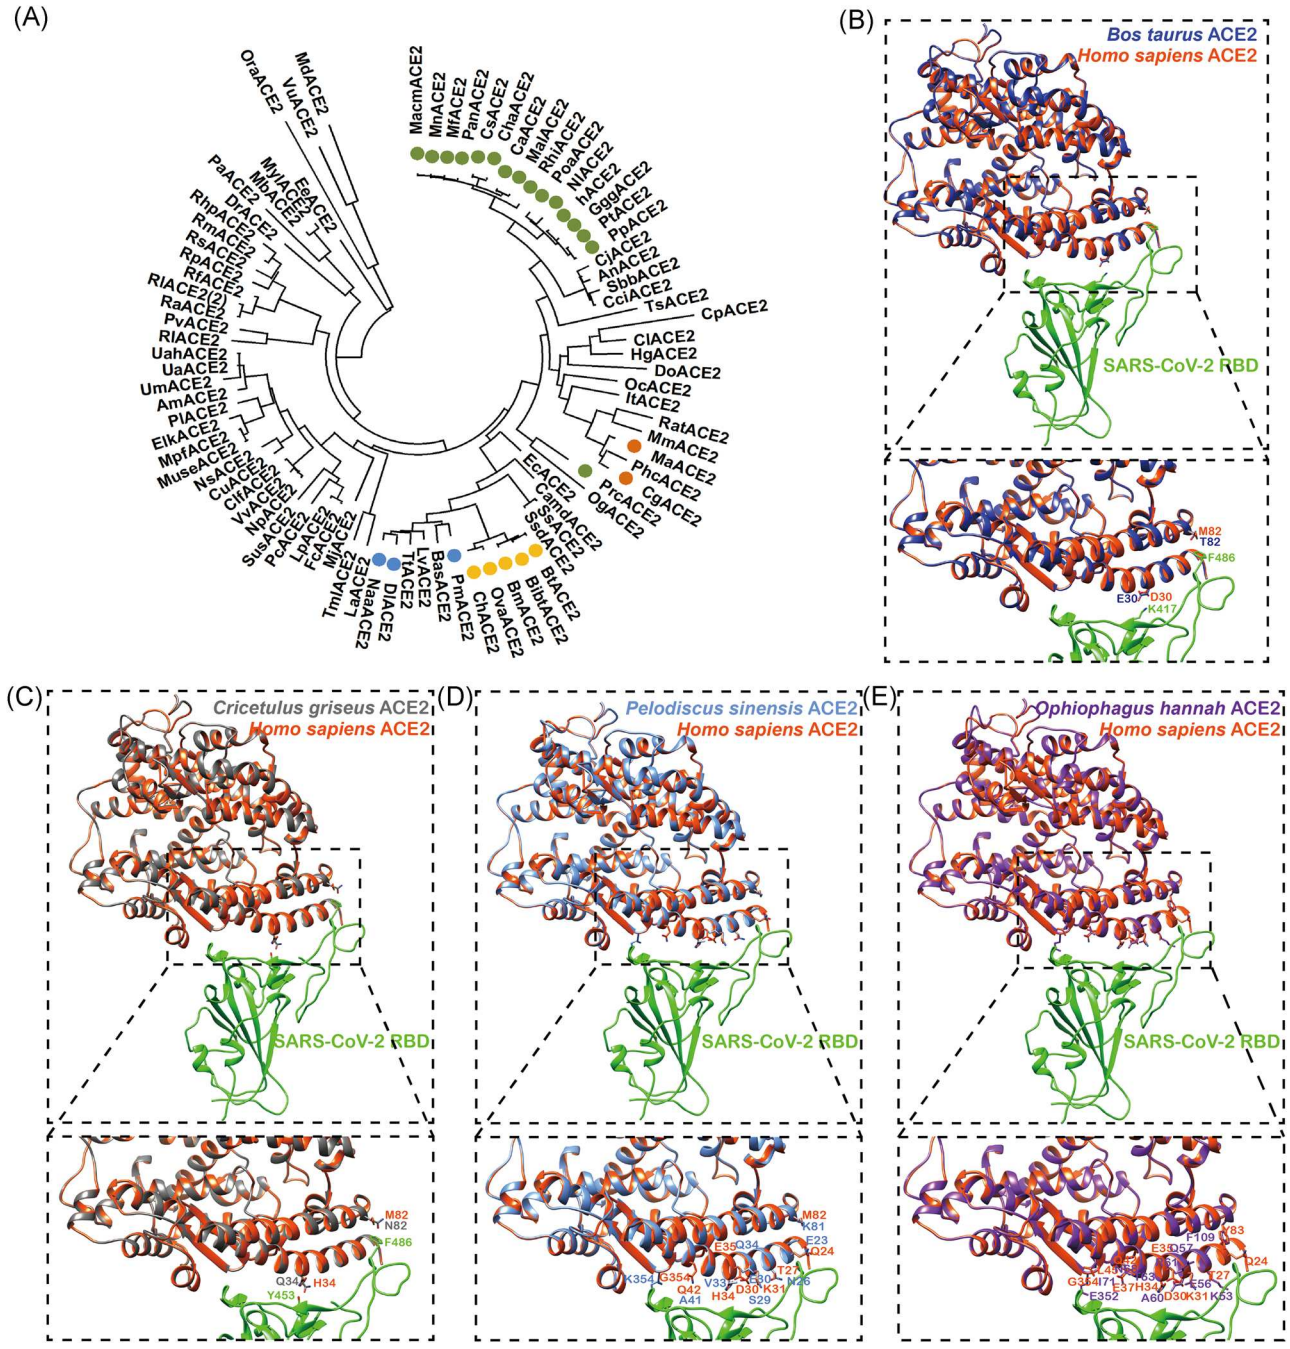

FIGURE 1 Structure simulation of SARS-CoV-2 RBD with ACE2 from different species. A, Phylogenetic tree of mammalian ACE2. ACE2 proteins from a total of 85 mammals were analyzed by MEGA-X and the phylogenetic tree was constructed using a maximum-likelihood method. The green, yellow, orange, and blue represent ACE2 from *Primates*, *Bovidae*, *Cricetidae*, and *Cetacea*, respectively. B, Structural simulation of the protein complex of *Bos taurus* ACE2 and SARS-CoV-2 RBD. *Bos taurus* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in medium blue, orange red, and green, respectively. C, Structural simulation of the protein complex of *Cricetulus griseus* ACE2 and SARS-CoV-2 RBD. *Cricetulus griseus* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in dim gray, orange red, and green, respectively. D, Structural simulation of the protein complex of *Pelodiscus sinensis* ACE2 and SARS-CoV-2 RBD. *Pelodiscus sinensis* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in cornflower blue, orange red, and green, respectively. E, Structural simulation of the protein complex of *Ophiophagus hannah* ACE2 and SARS-CoV-2 RBD. *Ophiophagus hannah* ACE2, *Homo sapiens* ACE2, and SARS-CoV-2 RBD are in purple, orange red, and green, respectively. ACE2, angiotensin-converting enzyme 2; MEGA-X, Molecular Evolutionary Genetics Analysis version X; RBD, receptor-binding domain; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2

3.2 | Structure simulation of the protein complex of SARS-CoV-2 RBD and *Bovidae/Cricetidae*/turtle/snake ACE2

Recently, the structure of SARS-CoV-2 RBD with human ACE2 has been resolved. To investigate whether *Bovidae/Cricetidae* ACE2 maintained the binding affinity with SARS-CoV-2 RBD, we simulated the potential structure of the protein complex. T82 and E30 in *Bos taurus* ACE2 kept the contact to F486 and K417 in SARS-CoV-2 S (Figure 1B). N82 and Q34 in *Cricetulus griseus* ACE2 maintained the contact to F486 and Y453 in SARS-CoV-2 S (Figure 1C). We concluded that *Bovidae/Cricetidae* ACE2 could associate with SARS-CoV-2 S (Figure 1B,C).

To investigate the potential association between SARS-CoV-2 and ACE2 from turtle and snake, we simulated the potential structure of turtle/snake ACE2 with SARS-CoV-2 RBD. The AA correlated to hACE2 Q42 is changed to A (A41) in turtle (Figure 1D). We also noticed that the AA correlated to hACE2 H34 is changed to A (A60) in a snake (Figure 1E). When the contact AA was mutated to smaller AA (A), the contact force for protein-protein interaction will be reduced. Moreover, the corresponding AA of K31 was changed to E (E30) in turtle and Q (Q57) in snake ACE2 (Figure 1D). K31 in hACE2 was critical for SARS-CoV RBD binding and ACE2-K31D mutant abolished its association with SARS-CoV RBD.[15] Taken together, turtle and snake ACE2 are unlikely to bind to S protein of SARS-CoV-2.

4 | DISCUSSION

SARS-CoV, MERS-CoV, and SARS-CoV-2 have caused severe human infectious diseases in the last 2 decades. These three human coronaviruses originated from bats, but the intermediate hosts were different. SARS-CoV came from the *Paguma larvata*,[16] and the intermediate host for MERS-CoV is *Camelus dromedaries*.[17] The new coronavirus SARS-CoV-2 has recently caused a serious pandemic in China and other countries. However, it is not clear which animals are involved in the evolution of SARS-CoV-2 and which animals may be infected by SARS-CoV-2. RBD region in S protein of pangolin coronavirus is similar to that of SARS-CoV-2,[7,8] indicating the involvement of pangolin in the recombination of SARS-CoV-2. By analyzing the codon usage of SARS-CoV-2, people suggested that snake might be a potential host for SARS-CoV-2.[9] Another study indicated that turtle is a potential intermediate host for SARS-CoV-2 based on the key AAs in ACE2 for interacting with SARS-CoV RBD.[10] The late study raised the concerns of SARS-CoV-2 infection in the turtle aquaculture and pet turtle. Most of the coronaviruses hosts are mammals; with a few of exceptions are birds. Considering that all known hosts for coronaviruses are thermostatic animals, it is unlikely that reptiles will be infected with SARS-CoV-2.

There are 20 key AAs in ACE2 critical for binding S protein of SARS-CoV-2.[11] On the basis of these 20 AAs, we analyzed the corresponding AAs in ACE2 from a list of mammal, bird, turtle, and snake. We found that the ACE2 of turtles and snake lost the capability to associate with S protein (Table 1 and Figure 1D,E). These reptiles should be ruled out from the potential host list for SARS-CoV-2. *Aves* ACE2 was unlikely to associate with SARS-CoV-2 RBD because they lost the critical K corresponding to K31 in human ACE2 (Table 1). Pangolin ACE2 was predicted to recognize SARS-CoV-2 RBD less efficiently because it only preserved 14 of 20 critical AAs (Table 1). Interestingly, we found that ACE2 proteins from *Primates*, *Bovidae*, *Cricetidae*, and *Cetacea* were capable to recognize RBD of SARS-CoV-2 by maintaining the majority of key residues in ACE2 for associating with SARS-CoV-2 RBD. Swine ACE2 (CpACE2) with 15 of 20 matched critical AAs was shown to support SARS-CoV-2 entry.[6] *Bovidae/Cricetidae* ACE2 matched more AAs than swine ACE2, thus they should recognize SARS-CoV-2 RBD. It would strengthen our conclusion if we have biochemical evidence for the S-ACE2 interaction analysis for *Bovidae/Cricetidae* ACE2. On the basis of human ACE2 and SARS-CoV-spike complex structure model (PDB ID: 2AJF), we and others recently predicted that hamster ACE2 could associate with SARS-CoV-2 and hamster might be a candidate small animal model for SARS-CoV-2 infection.[18,19] Indeed, golden Syrian hamster (*Mesocricetus auratus*) has been established as a model to study the pathogenesis and transmission of COVID-19.[19] One of *Cetacea*, *Neophocaena asiaeorientalis asiaeorientalis* (Yangtze finless porpoise), lives in the middle and lower reaches of the Yangtze River and its lakes, where Wuhan located nearby.[20] It will be interesting to investigate whether Yangtze finless porpoise could be infected with SARS-CoV-2 or related coronavirus.

In conclusion, we found that *Bovidae/Cricetidae* ACE2 but not turtle/snake ACE2 could recognize SARS-CoV-2 RBD. More attention should be paid to *Bovidae* and *Cricetidae* in hunting the potential intermediate host for SARS-CoV-2.

Hi Zhengli,

I hope your travel home was peaceful. I wanted to thank you for your attendance and presentation at the bat ID symposium. I think it was a very good meeting and I hope others benefited from it. We are already planning to host it again in 2020.

If you have an email distribution list for the conference you're hosting next year, could you please add me to it? It looks like a great meeting and if I can get travel arranged I would like to come.

Thank you,

Tony

Dear Tony,
Thank you very much for your information and organising the meeting!
Looking forward to meeting you!
Best regards,

Zhengli,

Hi Zhengli,

Yes, we are excited for the symposium. Quite a few more abstracts this time, so I am optimistic we can continue having the symposium at 3 year intervals.

Let me know if there's anything I can do to help you.

Thanks,

Tony

Hi Ben,

I have my flight booked and will arrive in Wuhan at 10:00 PM on October 19 (All Nippon Airways**NH 937**). Can you tell me the name and address of the hotel? I will need it for my visa and for my university administrators.

Thank you,

Tony

Hi Dr.Shountz:
There is no problem about the invitation letter with the official seal. I can prepare it today.
Is a scanned copy of this letter acceptable for visa application or the embassy must need an original copy?
Thanks
Ben

Hi Ben,

Did you get a PDF copy of the program? If not, I've attached it here.

The symposium was fantastic. We will probably have it again in 2020.

Thanks,

Tony

Dear Dr. Schountz:

The exciting conference is approaching. Although unfortunately I cannot attend the meeting due to the limited budget on international travel of our project, my colleagues, Prof. Zhengli Shi and Dr. Peng Zhou will go to Fort Collins and give two oral presentations.

May I ask for a pdf version of the conference program to forward to them?

Thank you so much!

Sincerely

Ben

Ben, I have attached a Word file that you can edit with the names and addresses of the four participants. So, just make a copy for each one and use them.

Thank you,

Tony

On Apr 11, 2017, at 3:56 AM, 鑀＄妵 <huben > wrote:

Dear Dr.Schountz:
I am a researcher at Wuhan Institute of Virology, Chinese Academy of Sciences. My colleagues and I are studying bat viruses and we have submitted four abstracts to the 2nd International Symposium on Infectious Diseases of Bats which is going to be held in Fort Collins in June.
The title for the 4 abstracts are:
1) SARS coronavirus may have originated from frequent recombination events betwwen SARS-like coronaviruses in a single horseshoe bat habitat (oral)
2) Dampening of STING-dependent IFN production: an implication of virus tolerance in bats? (oral) 锛墊 noticed from the web that this abstract has already been confirmed as oral presentation)
3) Genomic characterization of diverse BatCoV HKU10 and three novel alphacoronaviruses (poster)
4) Genetically diverse filoviruses in Rousettus and Eonycteris spp. bats, China, 2009 and 2015. (poster)
As it is a unique conference specializing on our research area, we are very eager to attend. However, it usually takes at least two months for us to get the US visa due to the complicated procedure of applying for travel permit to Chinese Academy of Sciences and then one month of administrative processing by US embassy. So in order we can make our visit to Colorado in late June, we have to start the process of travel permit and visa application now.
To apply for a travel permit, we are required to submit an invitation letter from the conference organizer. I know for the bat-borne disease meeting, we will know the results of the acceptance of the abstract by May. But it will be late for us to apply for the travel permit and US visa.
Could you please kindly provides four invitation letters to us indicating we will attend the meeting and give presentations? (oral or posters)
It does not matter whether the abstracts will be finally selected as he invitation letters are only for visa application.
We deeply appreciate your understanding and assistance.
Thank you very much!
Best regards

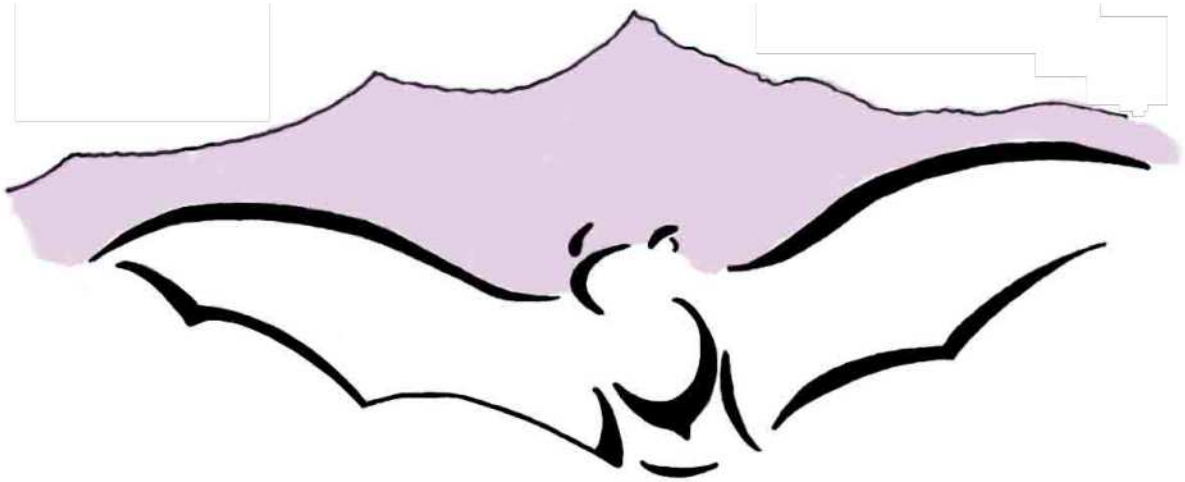
Infectious Diseases of Bats Symposium



June 29-July 1, 2017
University Center for the Arts
1400 Remington St
Colorado State University
Fort Collins, CO 80524

Table of Contents

Program

Venue: **University Center for the Arts**, Colorado State University

Thursday, June 29

5:30 p.m. Registration, PowerPoint file transfer, lobby, **University Center for the Arts**

6:00 p.m. Reception - *Wine, beer and snacks*, **University Center for the Arts**

Friday, June 30

7:00 a.m. Registration, University Center for the Arts

8:00 a.m. Tony Schountz. Colorado State University. **Welcoming remarks**

8:10 a.m. Session I - Filoviruses (Joseph Prescott, Moderator)

8:10 a.m. **Studies of horizontal transmission of Marburg virus among experimentally infected fruit bats**
Jonathan S. Towner[1,2], Amy J. Schuh[1], Brian R. Amman[1], Megan E. B. Jones[1,2], Tara K. Sealy[1], Uebelhoer LS, Spengler JR, Stuart T. Nichol[1]

[1]Viral Special Pathogens Branch, Centers for Disease Control and Prevention, Atlanta, USA, [2]Department of Pathology, College of Veterinary Medicine, University of Georgia, Athens, USA

8:30 a.m. **Investigations of Long-term Protective Immunity against Marburg Virus Reinfection in Egyptian Rousette Bats**
Amy Schuh, Amman BR, Sealy TK, Spengler JR, Nichol ST and Towner JS

Viral Special Pathogens Branch, Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA

8:45 a.m. **Innate immune response to filoviruses and the role of filoviral interferon-inhibiting domains in bat and human cells**
Ivan V. Kuzmin[1,2], Toni M. Schwarz[3], Philipp A. Ilinykh[1,2], Ingo Jordan[4], Thomas G. Ksiazek[1,2,5], Ravi Sachidanandam[6], Christopher F. Basler[3, 7], and Alexander Bukreyev[1,2,5]

Oral Presentation Abstracts

Studies of horizontal transmission of Marburg virus among experimentally infected fruit bats
Jonathan S. Towner[1,2], Amy J. Schuh[1], Brian R. Amman[1], Megan E. B. Jones[1,2], Tara K. Sealy[1], Uebelhoer LS, Spengler JR, Stuart T. Nichol[1]

[1]Viral Special Pathogens Branch, Centers for Disease Control and Prevention, Atlanta, USA, [2]Department of Pathology, College of Veterinary Medicine, University of Georgia, Athens, USA

Objectives: To investigate under experimental conditions the dynamics of Marburg virus replication in a known reservoir host and determine if 1) the virus can be transmitted from infected bats to immunologically naïve bats in the absence of arthropod vectors, and 2) identify the route(s) of virus shedding and therefore likely exposure. **Methods**: Using age-matched captive borne juvenile bats, we inoculated a total of 12 animals with Marburg virus 371 bat isolate and co-housed these animals with 24 naïve contact bats for 9 months under BSL-4 conditions and tested for evidence of virus shedding and transmission. **Results**: Marburg virus shedding was detected in oral, rectal and urine specimens from the inoculated bats through 19 days post infection. During the same time frame, Marburg virus was detected in oral specimens from contact bats, indicating that they were orally exposed to the virus from the inoculated animals. In the late study phase, we found that Marburg virus was horizontally transmitted from the donor bats to naïve contact bats by finding Marburg virus RNA in blood and oral specimens from contact bats, followed by the detection of Marburg virus IgG antibodies in these same animals. **Conclusions**: This study demonstrates, in the absence of any arthropod vectors, 1) direct filovirus transmission from a natural reservoir to another animal, 2) Marburg virus is shed primarily in saliva and urine, and perhaps feces, with some bats acting as super-shedders accounting for more than 80% of the cumulative virus shed, and 3) that this virus/reservoir host system can serve as an bona-fide experimental model for investigating how filoviruses are maintained long-term in nature and what drivers might influence occasional spillover to humans and other animals.

Investigations of Long-term Protective Immunity against Marburg Virus Reinfection in Egyptian Rousette Bats
Schuh AJ, Amman BR, Sealy TK, Spengler JR, Nichol ST and Towner JS

Viral Special Pathogens Branch, Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA

Objectives: The Egyptian rousette bat (ERB; *Rousettus aegyptiacus*) is as a known natural reservoir host for Marburg virus (MARV). Following infection of ERBs with MARV, virus-specific IgG antibodies rapidly decline and by 3 months post infection the bats are MARV seronegative. Therefore, it is unclear whether reinfection plays a role in MARV maintenance. **Methods:** To address this question, ERBs that had been “naturally” or experimentally infected with MARV 17 to 24 months prior were challenged with homologous virus. Following challenge, evidence of MARV replication in the blood and viral shedding from the oral mucosa was monitored for 14 days, MARV IgG antibody responses were monitored for 21 days and tissues obtained at necropsy at 21 days were tested for the presence of MARV RNA. **Results:** No evidence of MARV replication in the blood or shedding from the oral mucosa was detected in either group of bats through 14 days post inoculation. A robust MARV IgG antibody response occurred by seven days post inoculation in all bats, indicating the occurrence of a secondary immune response. **Conclusions:** This study demonstrates that both “natural” and experimental infection of ERBs with MARV induces long-term protective immunity against reinfection and suggests that other factors such as the twice-yearly influx of susceptible juveniles, large colony sizes and population connectivity, drive MARV transmission dynamics in wild populations of ERBs.

Innate immune response to filoviruses and the role of filoviral interferon-inhibiting domains in bat and human cells
Ivan V. Kuzmin[1,2], Toni M. Schwarz[3], Philipp A. Ilinykh[1,2], Ingo Jordan[4], Thomas G. Ksiazek[1,2,5], Ravi Sachidanandam[6], Christopher F. Basler[3, 7], and Alexander Bukreyev[1,2,5]

[1] Department of Pathology, The University of Texas Medical Branch, Galveston, Texas, USA, [2] Galveston National Laboratory, The University of Texas Medical Branch, Galveston, Texas, USA; [3] Department of Microbiology, Icahn School of Medicine at Mount Sinai, New York, New York, USA; [4] ProBioGen AG, Berlin, Germany; [5] Department Microbiology & Immunology, The University of Texas Medical Branch, Galveston, Texas, USA; [6] Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, New York, USA; [7] Current Address: Center for Microbial Pathogenesis, Institute for Biomedical Sciences, Georgia Research Alliance, Eminent Scholar in Virology, Georgia State University, Atlanta, Georgia, USA

Objectives: Innate immune responses in bat (Rousettus aegyptiacus) and human cells to the filoviruses Marburg (MARV) and Ebola (EBOV) were investigated to determine the ability of these viruses to subvert antiviral insults from different host species.
Methods: The innate immune response to filoviruses in bat and humans cells was profiled by deep sequencing and also analyzed by qRT-PCR. Bat mRNAs encoding IFNalpha, beta, gamma, lambda, and interferon stimulated genes (ISG) 54 and 56, were cloned and examined for their antiviral effect in response to MARV and EBOV infection in bat and human cells. Rates of infection and the effects of the major filoviral IFN-inhibiting domains (IID), VP35 and VP24, were analyzed in cells from both host species.
Results: We demonstrated that EBOV and MARV replicate to similar levels in all tested cell lines, indicating that permissiveness for EBOV at cell and organism levels do not necessarily correlate. Filoviruses, particularly MARV, induced a potent innate immune response in rousette cells that was generally stronger than in human cells. Both EBOV VP35 and VP24 IID were found to suppress the innate immune response in rousette cells, but only VP35 IID appeared to promote virus replication. Along with IFN-alpha and IFN-beta, IFN-gamma was demonstrated to control filovirus infection in bat cells but not in human cells suggesting host species specificity of the antiviral effect. The antiviral effects of bat IFNs appeared not to correlate with induction of bat ISG54 and ISG56, which were detected in human cells expressing bat IFN-alpha and IFN-beta.
Conclusions: Rousettus aegyptiacus cells mount robust innate immune responses to filovirus infection. Filovirus IIDs are active in both rousette and human cells; however, the VP35 IID plays a greater role in promotion of viral replication in rousette cells than in human cells. IFN-gamma plays a greater role in control of filovirus infections in rousette non-immune cells than in human cells. At least in part, the antiviral effect of IFN-gamma results from 'cross talk' leading to activation of the type I IFN response. The data are useful for understanding the interactions of filoviruses with natural (Rousettus aegyptiacus) and accidental hosts (humans).

Broad based surveillance for ebolaviruses: PREDICT in Sierra Leone, Liberia, and Guinea
Bird B[1], Goldstein T[1], Anthony S[2], Gbakima A[3], Saylors K[3], Jean Louis F[3], Wolking D[1], Epstein J[4], Karesh W[4], Kreuder-Johnson C[1], Mazet J[1]

One Health Institute UC Davis School of Veterinary Medicine[1], Center for Infection and Immunity Columbia University[2], Metabiota Inc.[3], EcoHealth Alliance[4]

Objectives: Developing and operationalizing strategies to reduce zoonotic pathogen spillover, amplification, and spread are nowhere more relevant than in Sierra Leone, Guinea, and Liberia. The devastating loss of lives associated with the Ebola virus outbreak revealed the urgent need for increased animal and public health sector capacity strengthening. Put into historical context, this epidemic was more than 60 times larger than any previous Ebola outbreak, spread to 7 additional countries, and stretched emergency response efforts to the utmost limits of capacity. **Methods**: PREDICT is working to improve understanding of wildlife reservoirs, spillover hosts, and origins of these viruses; ascertain the potential of virus-spillover into other non-typical hosts, such as livestock or companion animals; gain a greater understanding of high-risk human behavioral activities; and improve disease surveillance and laboratory capacities through workforce development in line with Global Health Security Agenda priorities. **Results**: Due to the impact on these three countries, USAID's PREDICT Project developed a focused effort to better address the threat of ebolaviruses by investigating the virus' animal origins, while strengthening in-country capacity to build and reinforce emerging disease surveillance and detection systems. In each country, teams are conducting concurrent sampling of from multiple animal taxa (dogs, cats, livestock, wildlife) and applying broad based molecular approaches to detect all known and other potential novel ebolaviruses. As of April 2017, over 6,500 animals have been sampled including over 3,500 bats in the three countries, with laboratory testing underway. Without identifying reservoirs of infection and how widely they are distributed across the region, prevention programs to reduce transmission from animals to people will have limited impact, and it is likely that future spillover of ebolaviruses from animals into humans will continue to occur. **Conclusions**: As we have seen over the years in Central and Eastern Africa where filovirus outbreaks have repeatedly occurred, effective control of these rare "spillover" events is possible and, when the right technical capacities are in place, these outbreaks can even be limited to a small number of human cases.

Quantifying signatures of resistance and tolerance to filoviruses in bat cell lines
Cara E. Brook[1], Melinda Ng[2], Esther Ndungo, Rohit K. Jangra, Andrew P. Dobson, Andrea L. Graham, Bryan T. Grenfell, C. Jessica E. Metcalf[1]*, Kartik Chandran[1]*

[1]Department of Ecology and Evolutionary Biology, Princeton University;
[2]Department of Microbiology and Immunology, Albert Einstein College of Medicine
*These senior authors contributed equally to this work.

Objectives: Previous work has demonstrated that a single amino acid change in the filovirus receptor, NPC1, in *Eidolon helvum* cells make them refractory to Ebola virus infection, hinting at a possible coevolutionary history between virus and bat host. We sought to expand on this nascent evidence of the evolution of pathogen resistance. **Methods:** We carried out a series of plaque assays, in which we challenged bat (EidNi/41.3, RoNi/7.1, PaKiT01), U2OS, and Vero cell lines with multicycle replicating pseudotype Ebola and Marburg filoviruses. Because of the agar overlay inherent to the plaque assay, viral transmission was restricted to neighboring cells. We visualized this transmission by photographing the timecourse of infection spread across the cell monolayer, and processing the images to quantify the proportion infected at a given time point as the proportion of photograph illuminated by GFP-tagged virus. We then fit spatially-structured traditional epidemiological models to the resulting data, in order to disentangle the mechanisms underpinning diverse trajectories of tolerance and resistance in different virus-cell line relationships. **Results:** Our modeling highlights diverse, species-specific evolutionary relationships between particular bat cell lines and particular filoviruses, which necessitate mechanisms of pathogen resistance in order to recapture data trajectories in some cases (chiefly *E. helvum* and Ebola and *P. alecto* and Marburg) and mechanisms of tolerance in others. **Conclusions:** Our work highlights the power of interdisciplinary approaches, combining quantitative epidemiology with cell biology and adds to growing evidence suggestive of unique species-specific coevolution between bats and filoviruses.

Serologic evidence of exposure to filoviruses in fruit bats, Singapore
Laing ED[1], Mendenhall IH[2], Linster M[2], Low DHW[2], Chen Y[2], Yan L[1], Sterling SL[1], Borthwick S[2], Neves ES[2], Lim JSL[2], Skiles M[2], Lee BPY[4], Wang LF[2], Broder CC[1], Smith GJD[2, 5]

Uniformed Services University, Bethesda, MD, USA[1], Duke-National University of Singapore Medical School, Singapore[2], North Carolina State University, Raleigh, NC, USA[3], National Parks Board, Singapore[4], Duke Global Health Institute, Duke University, Durham, North Carolina, USA[5]

Objectives: Bats are known natural hosts of Nipah virus and Maburg virus, and the collective evidence suggests that bats are also the natural hosts of ebolaviruses. Reston virus, an *Ebolavirus* species, is known to circulate in species of bats in the Philippines. To examine whether ebolaviruses and marburgviruses are more broadly present in Southeast Asia, we tested sera from three fruit bat species endemic in Singapore and widely distributed throughout Southeast Asia for evidence of past exposure to known species of ebolaviruses and marburgviruses. **Methods:** Sera were collected from the above-mentioned bat species from 2011 to 2016 in Singapore to screen for evidence of exposure to filoviruses. Venous blood was diluted 1:10 in 1×PBS and tested using a Bio-Plex® bead-based multiplex assay that simultaneously probes sera for immunoglobulins specific to the viral envelope glycoprotein from representative strains of all previously described *Ebolavirus* and *Marburgvirus* spp. We employed methods developed by Peel AJ *et al.* to establish a median fluorescence intensity (MFI) cutoff value. We screened 409 samples with this *Ebolavirus/Marburgvirus* spp. Bio-Plex® assay. **Results:** Positive results indicated that bats were previously infected with viruses related to the ebolaviruses from which the virus surface proteins were derived. Of the species tested, 10% of *Eoncyteris spelaea*, 8% of *Cynopterus brachyotis*, and 4% of *Penthetor lucasi* had positive sera results for antibodies specific to ebolaviruses.
Conclusion: These serological results demonstrated that viruses related to ebolaviruses have previously infected all three species of fruit bats, and may circulate in the populations, but we have not detected the virus in any samples. We conducted next generation sequencing on urine and feces, bat cell lines and screened numerous samples from bats in Singapore and have detected no evidence of the virus. As there is no evidence of Ebola virus disease in humans in Singapore or Southeast Asia, we think that these serological findings are evidence of novel, yet undescribed viruses related to known ebolaviruses.

Predicting undiscovered filovirus reservoirs and patterns of disease emergence
David Hayman[1]

[1]Molecular Epidemiology and Public Health Laboratory, Hopkirk Research Institute, Massey University, New Zealand

Objectives: How can we discover unidentified filovirus hosts and where should we be searching for the viruses? Filoviruses *Ebolavirus* (EBOV) and *Marburgvirus* cause hemorrhagic fevers with high mortality rates, posing significant threats to public health and wildlife conservation. The viruses have sporadically emerged over the last 40 years at least, and yet the hosts of EBOV in particular remain poorly known and characterized. Here different studies help inform field surveillance through the identification of bat traits that predict filovirus reservoirs and ecological processes that facilitate emergence. **Methods:** Different modeling approaches were used. A mathematical model with seasonal birthing synthesized filovirus and bat data to determine if biannual birthing

might facilitate pathogen persistence. Regression analyses on serological data tested the model predictions. A machine learning approach provided additional information on bats, integrating multiple host trait data. Fragmentation analyses using satellite land cover data and Ebola virus disease outbreak index cases in humans (i.e. spillover from wildlife reservoirs) tested the hypothesis that forest fragmentation was correlated with emergence. **Results:** Synthesis of filovirus and bat data through models suggests bi-annual breeding and longer incubation periods, such as reported for Egyptian fruit bats and EBOV in experimental studies, allow viral persistence in bat colony sizes often found in nature. Serological data and machine learning approaches support the findings, with bats from species with two annual birth pulses more likely to be seropositive (odds ratio 4.4, 95% confidence interval 2.5-8.7) than those with one, suggesting biannual birthing may allow filovirus persistence. Machine learning algorithms suggest species' geographic range overlap may facilitate filovirus persistence. Finally, fragmentation analyses suggest Ebola virus disease outbreaks occurred mostly in hotspots of forest fragmentation. **Discussion:** These analyses suggest surveillance for filoviruses, especially ebolaviruses, might be targeted to young bats from species with biannual birthing in areas of fragmented forested habitat. The link between forest fragmentation and EBOV outbreaks suggests there is common ground between biodiversity conservation and disease risk mitigation. Together these results will help the research community identify where, when and in which species to continue the search for filovirus hosts.

Bats as possible animal origin of MERS-CoV

Susanna K. P. Lau

Department of Microbiology, The University of Hong Kong, Hong Kong, China

Objectives: Bats are important reservoir for emerging viruses including coronaviruses. Although dromedary camels are believed to be the immediate animal source of the recent MERS epidemic, the evolutionary origin of MERS-CoV remains obscure. While horseshoe bats are the primary reservoir of ancestors of SARS-CoV, the possible role of bats in the emergence of MERS-CoV is less clear. When MERS-CoV was first discovered, it was found to be most closely related to *Tylonycteris* bat CoV HKU4 (Ty-BatCoV HKU4) and *Pipistrellus* bat CoV HKU5 (Pi-BatCoV HKU5) previously discovered in lesser bamboo bat (*Tylonycteris pachypus*) and Japanese pipistrelle (*Pipistrellus abramus*) respectively in Hong Kong. Subsequently, two other lineage C betacoronaviruses, BtVs-BetaCoV/SC2013 and Coronavirus Neoromicia/PML-PHE1/RSA/2011 (NeoCoV) were also detected in bats from China and Africa respectively. Interestingly, a lineage C betacoronavirus, Erinaceus CoV VMC/DEU, has also been found in European hedgehogs, which are phylogenetically closely related to bats, in Europe. Although NeoCoV represents the closest bat counterpart of MERS-CoV in most genome regions, the spike (S) protein, important for host receptor binding, is genetically divergent from that of MERS-CoV. On the other hand, Ty-BatCoV HKU4 possessed an S protein being most closely related to MERS-CoV. The spike of Ty-BatCoV HKU4, but not that of Pi-BatCoV HKU5, was able to utilize the MERS-CoV receptor, human dipeptidyl peptidase 4 (hDPP4) or CD26, for cell entry. These findings suggested that bats may be the primary host of the ancestor of MERS-CoV. **Methods**:To better understand the evolutionary path of MERS-CoV, we collected bat samples from various regions in China. **Results**: Diverse CoVs were detected, including a potentially novel lineage C betacoronavirus. Compared to Ty-BatCoV HKU4 and Pi-BatCoV HKU5, the virus was even more closely related to MERS-CoV and NeoCoV in most regions of its genome. In contrast, the S1 region was less closely related MERS-CoV than Ty-BatCoV HKU4 but more closely related to MERS-CoV than Pi-BatCoV HKU5. To determine if this virus can utilize hDPP4 as receptor, binding experiments using S1-receptor-binding domain (RBD), cell entry studies using pseudovirus assays and structural modelling of the RBD-hDPP4 interphase were performed. **Conclusions**: The results suggested a stepwise evolutionary process among lineage C betacoronaviruses in gaining the ability to bind hDPP4, and support a bat origin of MERS-CoV.

Rapid detection of MERS coronavirus ancestors in bats

Prof. Patrick CY Woo, Department of Microbiology, The University of Hong Kong, Hong Kong.

Objectives: Since its first appearance in 2012, the Middle East Respiratory Syndrome (MERS) has affected more than 25 countries in four continents with more than 1,300 cases and a high fatality rate of more than 30%. A novel lineage C betacoronavirus (betaCoV), MERS-CoV, has been confirmed to be the etiological agent. Human dipeptidyl peptidase 4 (hDPP4) was found to be the cellular receptor for MERS-CoV. Subsequent detection of MERS-CoV and its antibodies in dromedaries in various countries in the Middle East and North Africa have implied that these animals are probably the reservoir for MERS-CoV. Other lineage C betaCoVs in bats [e.g. *Tylonycteris* bat CoV HKU4 (Ty-BatCoV-HKU4), *Pipistrellus* bat CoV HKU5 (Pi-BatCoV-HKU5)] and hedgehogs were found to be closely related to MERS-CoV. So far, detection of MERS-CoV and discoveries of its closely related CoVs are most efficiently achieved through RT-PCR. Although RT-PCR is highly sensitive, its turn-around-time is about four hours and the test requires expensive equipment, stringent laboratory set-up and personal attention to prevent laboratory PCR product cross contamination which may lead to false-positive results.

Methods: Recently, we have developed a monoclonal antibody-based rapid nucleocapsid protein (NP) detection assay for on-site diagnosis of MERS-CoV, which can be finished in 30 minutes. **Results and Conclusions**: This rapid test is highly specific for MERS-CoV for human and dromedary samples, as samples containing other human CoVs (HCoV-OC43, HCoV-229E, HCoV-NL63 and HCoV-HKU1) or dromedary CoV UAE-HKU23 all showed negative results. However, we hypothesize that the rapid test can pick up betaCoVs closely related to MERS-CoV; and hence would be useful for the discovery of MERS-CoV ancestors. To test this hypothesis, we examine the usefulness of this rapid test to detect four alphaCoVs and four lineage B, C and D betaCoVs in fecal samples of bats.

Global patterns in coronavirus diversity

One Sutter, Suite 600, San Francisco, CA, 94104 (USA); [7]Wildlife Conservation Society, New York, NY, (USA); [8]= http://www.vetmed.ucdavis.edu/ohi/predict /publications/Authorship.cfm

Objectives: Since the emergence of SARS-CoV and MERS-CoV it has become clear that bats are important reservoirs of coronaviruses (CoVs). Despite this, only 16% of all CoV sequences in Genbank come from bats. The remaining 84% largely consist of known pathogens of public health or agricultural significance, indicating that current research effort is heavily biased towards describing known diseases rather than the 'pre-emergent' CoV diversity circulating in bats. Our study addresses this critical gap, and focuses on the evolutionary and ecological drivers of CoV diversity in resource poor countries, where the risk of zoonotic emergence is believed to be highest. **Methods**: We surveyed the diversity of CoVs in multiple host taxa from 20 countries in Africa, Asia and Latin America to explore the factors driving viral diversity at a 'global' scale. Partial CoV sequences were identified using consensus PCR, which was chosen in part because it could be easily implemented in resource poor settings. Sequences were then parsed into phylogenetic clusters (operational taxonomic units) and analyzed using ecological and epidemiologic approaches. **Results**: In total we identified sequences representing 100 discrete clusters, 91 of which were found in bats, and showed that patterns of CoV diversity correlate with those of bat diversity. This cements bats as the major evolutionary reservoirs and ecological drivers of CoV diversity. Preliminary co-phylogenetic reconciliation analysis indicated that frequent host switching has contributed to CoV evolution, and that regional variation exists in the dynamics of this process. **Conclusions**: Overall our study represents a model for exploring global viral diversity and advances our fundamental understanding of CoV biodiversity and the potential risk factors associated with zoonotic emergence.

SARS coronavirus may have originated from frequent recombination events between SARS-like coronaviruses in a single horseshoe bat habitat

Ben Hu[1], Lei-Ping Zeng[1], Xing-Lou Yang[1], Xing-Yi Ge[1], Wei Zhang[1], Bei Li[1], Dong-Sheng Luo[1], Yun-Zhi Zhang[2], Mei-Niang Wang[1], Peter Daszak[3], Lin-Fa Wang[4], Jie Cui[1], Zheng-Li Shi[1]

[1] CAS Key Laboratory of Special Pathogens and Biosafety, Center for Emerging Infectious Diseases, Wuhan Institute of Virology, Chinese Academy of Sciences, Wuhan, China; [2]Yunnan Institute of Endemic Diseases Control and Prevention, Dali, China; [3]EcoHealth Alliance, New York City, New York, USA; [4]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore.

Objectives: Horseshoe bats are recognized as the natural reservoirs of Severe Acute Respiratory Syndrome coronavirus (SARS-CoV), as an increasing number of SARS-like coronaviruses (SL-CoV) have been detected in this bat family since 2005. However, knowledge gaps remain between currently known bat SL-CoVs and the direct progenitor of SARS-CoV. Further information is needed to better understand where and how SARS-CoV originated from bat reservoirs. **Methods:** We have conducted a 5-year surveillance of SL-CoV in a cave inhabited by horseshoe bats in Yunnan, China. Full-length genome sequencing of 11 novel bat SL-CoVs discovered in this single location was performed and genomic characterization, phylogenetic analysis and recombination analysis were conducted. Efficiency of human ACE2 usage was also evaluated in HeLa cells for several newly identified strains. **Results:** Our findings revealed that genetically diverse bat SL-CoVs were circulating in this single location, including different strains with high sequence similarity to SARS-CoV in the highly variable N-terminal

domain (NTD) and receptor-binding domain (RBD) of S protein and the ORF8 region, respectively. Meanwhile, compared with other SL-CoVs, strains identified from this cave exhibited higher sequence similarity to SARS-CoV in the non-structural proteins. Evidence supported that frequent recombination events have occurred within the S gene and around ORF8 between bat SL-CoVs in this cave and may have promoted the generation of the pandemic SARS-CoV. Cell entry studies demonstrated that different newly identified SL-CoVs with variants of S protein are all able to use human ACE2 as the receptor, which represent a potential risk of emergence if given the opportunity to spillover. **Conclusions:** We have identified an epicenter of SL-CoVs where the director progenitor of SARS-CoV likely originated via sequential recombination events. These findings offered important new insight into understanding the geographical and evolution origin of SARS-CoV and highlights the need to pursue the surveillance of bat SL-CoVs to make better preparation for future emergence of SARS-like disease in humans.

A metagenomic approach identifying a MERS-related coronavirus in a bat from South Africa

Marike Geldenhuys[1], Marinda Mortlock[1], Jaqueline Weyer[2], Oliver Bezuidt[3], Ernest Seamark[4], Teresa Kearney[5,6], Cheryl Gleasner [7], Tracey Erkkila[7], Helen Cui[7] and Wanda Markotter[1]

[1]Centre for Viral Zoonosis, Department of Medical Virology, Faculty of Health sciences, University of Pretoria, Pretoria, South Africa; [2]Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, South Africa; [3]Centre for Microbial Ecology and Genomics, University of Pretoria, Pretoria, South Africa; 4AfricanBats NPC, South Africa and Centre for Wildlife Management, University of Pretoria, Pretoria, South Africa; [5]Animal, Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa; [6]Ditsong Museum of Natural History, Pretoria, South Africa; [7]Los Alamos National Laboratory, New Mexico, USA

A Middle East Respiratory Syndrome (MERS) related coronavirus was previously detected in a Cape serotine bat (*Neoromicia capensis*) from the KwaZulu Natal Province in South Africa. Though the virus showed significant similarity to human MERS coronavirus (MERS-CoV), it was too divergent to be considered the direct progenitor of the virus causing human MERS-CoV outbreaks. **Objectives:** As part of a broader viral discovery surveillance program investigating excreted zoonotic viruses from bats, we implemented metagenomic techniques to collectively screen the virome of 60 *Neoromicia* bats constituting 6 species from 4 South African provinces sampled from 2007-2015. **Methods:** Using a viral particle enrichment methodology, total nucleic acids from faecal and rectal specimens were sequenced on Illumina's MiSeq and NextSeq500. Coding complete genome sequencing was performed with further amplicon sequencing on Illumina's MiSeq. Bayesian (BEAST) phylogenetic comparisons and pairwise estimations were performed with full genome representatives of all 4 betacoronavirus lineages. **Results:** We detected a MERS-related betacoronavirus from the same *Neoromicia* species. The virus shared a 97.2% overall nucleotide identity to another *Neoromicia* MERS-related virus identified in South Africa, and 85.5-85.6% nucleotide identity to human and camel (alternative hosts) strains of MERS-CoV. Significant discrepancies between bat-borne and human/camel MERS-CoV genomes were attributed to the low (63.7-64.3%) amino acid similarities of the spike genes, which is responsible for receptor attachment. Genome comparisons between betacoronavirus lineages of emerging viruses, namely MERS-CoV and the equivalent Severe Acute Respiratory Syndrome (SARS) coronaviruses, indicate that the relative phylogenetic distances between *Neoromicia* MERS-related strains and human/camel MERS-CoV are far greater than the distances between SARS-related bat viruses and human SARS viruses. **Conclusions:** Continued surveillance within the *Neoromicia* genus may yield additional MERS-related viruses sharing greater similarity to the human and camel MERS strains (as was shown with detected SARS-related bat viruses). Alternatively, if the progenitor of MERS-CoV originated from the *Neoromicia* genus, the currently identified diversity would suggest that significant receptor adaptation was required within dromedary camels (or unknown intermediate hosts) prior to being transmitted to humans. Continued viral surveillance in regions inhabited by both these hosts may aid in understanding the emergence of MERS.

New insights into the antiviral innate immune response of *Desmodus rotundus*

Sarkis Sarkis, Marie-Claude Lise, Edith Darcissac, Stéphanie Dabo, Christine Neuveut, Benoît de Thoisy, Eliane Meurs, Anne Lavergne and Vincent Lacoste

Institut Pasteur de la Guyane

The common vampire bat, *Desmodus rotundus*, is the main reservoir of rabies virus in South America. Mechanisms that allow persistence of viruses in bats are not well-defined. During the last decade, innate immunity has emerged as one of the implicated mechanisms. As a non-model organism, no tools were available regarding *D. rotundus*, there was therefore a crying need for characterizing their immune system. Given that the interferon (IFN) system provides the first line of defense upon viral recognition, we investigated the IFN-I response in an immortalized cell line, established from a *D. rotundus* embryonic lung, stimulated with synthetic

dsRNA (poly I:C). We observed that stimulation induced high levels of expression of all PRRs involved in dsRNA recognition, as well as a rapid up-regulation of both IFN-α1 and β. Furthermore, in characterizing some of the ISGs such as OAS1, PKR and ADAR, we identified two OAS1 genes, tentatively named *OAS1a* and *OAS1b*. Upon stimulation, *OAS1b* appeared to be the most inducible ISG tested. These results not only provide evidence of the intact signaling pathway of the IFN-I in our cellular model, but also that *OAS1b* may be a major player in antiviral activity in *D. rotundus*. In the frame of the present work, we generated a sum of insightful tools specific of the common vampire bat useable to the study of a number of different viruses, the first of which is the rabies virus.

A comparative study of the autophagy pathway during virus infection of bat (natural) and human (accidental) host cells

Eric D. Laing[1], Spencer L. Sterling[1], Dawn L. Weir[1], Sasha E. Larsen[2], Linfa Wang[3], Brian C. Schaefer[1], and Christopher C. Broder[1]

[1]Department of Microbiology, Uniformed Services University, Bethesda, MD, USA; [2]Department of Pharmacology, Uniformed Services University, Bethesda, MD, USA; [3]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore

Objectives: In contrast to other terrestrial animals, infection of bats with ebolaviruses and henipaviruses does not cause symptomatic disease. Whether bats have antiviral mechanisms to control these infections or how these viruses persist at a cellular level is largely unknown. Autophagy is a cellular protein homeostatic process, which has been implicated as a cell-autonomous innate defense mechanism against a broad array of intracellular infections. Bats are longer lived compared to other similarly sized mammals and increased proteostatic processes have been observed in long-lived mammalian species. **Methods:** In this study, we performed an investigation of autophagy in cell lines from the black flying fox (*Pteropus alecto*), a natural host of Hendra virus and Australian bat lyssavirus (ABLV), and human cells. ABLV, a neurotropic virus, was used as a model bat-borne virus to examine the interactions between an intracellular virus infection and autophagy in host cells. **Results:** Autophagy activation was observed in *P. alecto* brain tissue-derived primary and secondary cells infected with replication competent ABLV 1 and 2 days post infection. Compared to a human neuroblastoma cell line, *P. alecto* kidney and brain cells exhibited a higher level of basal autophagy. Treatment of bat and human cell lines with pharmacological activators of autophagy reduced ABLV replication. Quantification of ABLV titers and protein levels after infection of bat and human cells lines demonstrated that bat cells were less permissive to ABLV infection. Lentiviral knockdown of autophagy-related gene-5 (ATG-5) in bat and human cell lines did not result in a significant silencing of the autophagy pathway, however, a trending increase of ABLV replication levels was observed in the ATG-5 knockdown cells. Pre- and post-infection treatment of human neuroblastoma cells with BEZ235, an mTOR- and PI3K-inhibitor, significantly decreased virus replication in a dose-dependent manner. **Conclusions:** To our knowledge this is the first study to explore whether the autophagy pathway has a role as an antiviral defense mechanism during virus infection in bats. Ongoing experiments aimed at the interplay between autophagy and apoptosis will be critical to supporting our hypothesis that autophagy is an antiviral defense mechanism in bats.

Development of a minimally invasive individual identification technique for continuous monitoring of African bat species

Stewart McCulloch[1]; Teresa Kearney[2,3,4]; Ernest Seamark[3,5]; Janusz Paweska[6]; and Wanda Markotter[1]
[1] Centre for Viral Zoonoses, Department of Medical Virology, Faculty of Health Sciences, University of Pretoria, South Africa; [2] School of Animal, Plant and Environmental Sciences, University of Witwatersrand, Private Bag 3, Wits 2050, South Africa [3] AfricanBats, 357 Botha Ave, Kloofsig, 0157, Pretoria, South Africa; [4] Ditsong National Museum of Natural History, Pretoria, South Africa; [5] Centre for Wildlife Management, Faculty of Natural and Agricultural Sciences, University of Pretoria, South Africa, 0001; [6] Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, Johannesburg, South Africa.

Objectives; An ever increasing number of potentially zoonotic diseases are associated with bat populations throughout the world, and as such the continuous monitoring and surveillance of these populations has become essential, not only for disease epidemiology but also in order to address the lack of knowledge available for biology, ecology and life histories of the majority of bat species. This requires the development of an ethically acceptable, cost effective, durable and reliable marking system to facilitate monitoring of individual bats. In order to address annual population structure, potential movement patterns and individuals' infection or exposure status we tested the ability to uniquely mark 11 bat species from six families, ranging in mass from 4g to 120g, using wing tattoos. Specific serological monitoring of Lagos bat virus exposure in *Rousettus aegyptiacus,* focussing on the presence and duration of neutralising antibodies has been undertaken since 2012. **Methods;** Non-toxic black ink was applied into the interdermal layers of the propatagial membrane of the bat by means of a tattoo system with nine-pronged needles. The tattooing procedure was performed on individual bats from a captive colony of *R.*

aegyptiacus (n=287) and free-flying, wild populations of the aforementioned species (n=2559). The robustness and longevity of this system was assessed from recaptures of tattooed individuals representing four of the above species in the wild, and observations of the captive colony of *R. aegyptiacus*. **Results;** This technique provides a simple, durable and cost effective marking system for both immediate and medium term monitoring, with no observed detrimental effects to the individuals to date. The longest periods between application and observation of tattoos has been; 927 days for *R. aegyptiacus*, 292 days for *N. thebaica*, 126 days for *M. natalensis* and 89 days for *Rh. smithersii.* Over 100 *R. aegyptiacus* recapture events have demonstrated individuals' seroconversion, antibody maintenance and loss against LBV. **Conclusion;** This technique has shown potential to facilitate monitoring individual bats' infection or exposure status in both captive and wild settings, with individual seroconversion and titer loss against LBV being observed, as well as providing an effective mark-recapture identification for population and movement studies.

Characterization of a novel Rhabdovirus isolated from insectivorous bat (*Pipistrellus kuhlii*) in Italy
Davide Lelli[1], Alice Prosperi[1], Chiara Chiapponi[1], Paola Debenedictis[2], Anna Maria Gibellini[3], Stefania Leopardi[2], Enrica Sozzi[1], Dino Scaravelli[4], Ana Moreno[1], Antonio Lavazza[1]

[3]Wildlife Rehabilitation Center WWF of Valpredina via Pioda n.1, 24060 Cenate Sopra(BG), Italy
[4]University of Bologna, Department of Veterinary Medical Sciences, via Tolara di sopra 50 - 40064 Ozzano Emilia (BO), Italy

Objectives: *Rhabdoviridae* is one of the most ecologically diverse families of RNA viruses with clinical importance. Herein we report the isolation and the genome characterization of a novel rhabdovirus detected from a bat collected within a survey implemented in Italy on emerging viruses of bats. **Methods:** A fresh carcass of an adult female of *Pipistrellus kuhlii* spontaneously dead in a wildlife rehabilitation center in Northern Italy was fully necropsied. Tissue samples from different organs (lung, hearth, intestine) were subjected to viral isolation on cell culture. Virus identification was performed using negative staining electron microscopy (nsEM) and NGS sequencing. Molecular and phylogenetic analyses were performed. **Results:** Anamnesis reported sensory depression, inappetence, normal body mass and injuries of patagium consistent with a cat bitten. The death occurred three days after the admission to the rehabilitation center and no pathological lesions indicative of infectious diseases were observed at necropsy. CPE was observed on VERO cells inoculated with a pool of organs and nsME performed on cells supernatants revealed characteristic bullet-shaped viral particles referable to rhabdovirus. Tests aimed to exclude rabies and related lyssaviruses resulted negative. The complete genome size was 11,780 nt comprised 5 genes encoding the canonical rhabdovirus structural proteins and an additional transcriptional unit (U1) encoding a small protein (157 aa) located between the G and L genes (3'-N-P-M-G-U1-L-5'). BLAST analysis showed the highest nucleotide identity (65%) to Le Dantec virus (LDV) (human, 1965 Senegal) the prototype strain of the putative genus Ledantevirus. The most highly conserved protein L shared 70% and 69% of aa identity with LDV and Keuraliba virus (KEUV) (gerbil, 1968 Senegal) respectively. Phylogenetic tree based on full-genome sequence confirm the belonging of the new isolate to the ledantevirus group. **Conclusions:** A novel rhabdovirus was identified from *Pipistrellus kuhlii*, the most common species in urban areas in Italy. This finding represents (beside lyssaviruses) the only bat-borne rhabdovirus isolated in Europe. Specific diagnostic tools for viral detection will be set up for epizootiological investigations aimed to define the viral ecology and diffusion in bats population in Italy, in order also to further characterize and clarify its zoonotic potential.

Age-specific dynamics of maternally- and infection- derived immunity within African bat populations
Alison J Peel[1], Kate S Baker[2], David TS Hayman[3], Andrew A Cunningham[4], James LN Wood[5], Romain Garnier[5] and Olivier Restif[5]

[1] Environmental Futures Research Institute, Griffith University, Nathan, QLD, Australia; [2] Institute for Integrative Biology, University of Liverpool, UK; [3] Molecular Epidemiology and Public Health Laboratory, Hopkirk Research Institute, Massey University, Palmerston North, New Zealand; [4] Institute of Zoology, Zoological Society of London, Regent's Park, London, UK; [5] Department of Veterinary Medicine, University of Cambridge, Cambridge, UK

Objectives: Predicting and managing spillover of emerging infectious diseases to domestic animals and humans depend on data on reservoir host distribution, ecology and immunology as well as the mechanisms governing pathogen transmission among its populations. However, such data are generally sparse. This is exemplified by old-world fruit bats, which have been linked to an increasing number of zoonotic viruses, but whose ecology is

challenging to study and immunology has only recently begun to be elucidated. Even where appropriate data are available, fission-fusion population structures make it challenging to separate out the dynamical effect of pathogen reintroduction into the study population through movement from the transmission dynamics expected within a closed population. Island populations provide ideal natural experiments and involve simplifications analogous to the assumptions often made in modelling studies (e.g. single, closed population of a single species), allowing exploration of underlying processes. Here, building on an extensive body of work on straw-coloured fruit bats (*Eidolon helvum*), we aim to further elucidate fundamental processes governing viral dynamics, including the role of maternally-derived antibodies (MatAb). **Methods:** We focus on two viruses for which *E. helvum* is a reservoir (Lagos bat virus (LBV) and African henipavirus) and look for evidence of the presence of MatAb in wild *E. helvum* from continental and island populations. We use rare age-specific data to model waning rates of maternally- and infection- derived antibodies. These results then informed the parameterisation of a stochastic seasonal birth model to explore population-level persistence in the presence of MatAb, in both naive and non-naive populations. **Results:** Statistical modelling supported age as the strongest determinant of seroprevalence for both henipavirus and LBV, in addition to highly significant correlations between mother-offspring pairs. Age-specific seroprevalences predicted rapid loss of maternal immunity and effectively lifelong infection-induced immunity (particularly for LBV). The inclusion of MatAb had considerable implications on viral persistence within populations in a dynamic birth pulse model. **Conclusions:** This study helps to better understand endemic viral dynamics in bat populations, and the implications of considering the presence of MatAb in broader wildlife disease systems.

Detection of rubula- and related viruses in an Egyptian fruit bat (*Rousettus aegyptiacus*) colony in South Africa

Marinda Mortlock[1], Jacqueline Weyer[2], Janusz Paweska[2] and Wanda Markotter[1]

[1]Centre for Viral Zoonoses, Department of Medical Virology, Faculty of Health Science, University of Pretoria, South Africa; [2]Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, Johannesburg, South Africa

Objectives: More than 22 viral families have been associated with bats globally, eight of which with the Egyptian fruit bat (*Rousettus aegyptiacus*) occurring across sub-Saharan Africa and parts of the Middle East. Among numerous other zoonotic viruses, this species has also been associated with zoonotic henipaviruses (family *Paramyxoviridae*). More recently, a newly described zoonotic rubulavirus, Sosuga virus, was detected in this species from Uganda. The occurrence and diversity of these viruses remain unknown in Southern Africa. **Methods:** A broadly reactive hemi-nested RT-PCR assay targeting the *Avula-Rubulavirus* genera within the *Paramyxoviridae* family was used for nucleic acid detection. Spleen and kidney samples from bats collected during 2012-2016 from a cave in the Limpopo Province of South Africa, were retrospectively screened for the presence of rubulavirus RNA. Virus isolation, next-generation Illumina sequencing and amplicon sequencing were used to obtain full gene or genome sequences for comparison. **Results:** A total number of 137 bats were screened of which 5.84% of spleen samples tested positive. We detected several rubulavirus-related viruses grouping in a sister clade to the *Rubulavirus* genus. This clade contains other bat-associated rubulaviruses including the zoonotic Sosuga virus. Additionally, a co-infection with a virus closely related to human mumps virus was detected in one of the bats sampled. Preliminary results also suggest seasonality of these viruses in the colony, as positive individuals were predominantly detected in winter months. This phenomenon coincides with the loss of maternal antibodies i.e. an influx of susceptible individuals into the colony. **Conclusion:** The first evidence of bat-associated rubulaviruses from *R. aegyptiacus* in South Africa, some of which are related to know human pathogens, are reported. Additionally, a considerable diversity was detected from a small sample size. Enhanced surveillance might shed light on the prevalence of these viruses within the targeted colony. Considering the potential excretion of these viruses during the winter months might be the next step in determining their transmission potential. This is of importance as the specific cave is situated within a rural settlement surrounded by free-roaming livestock and is frequented by humans for religious practices.

Influenza-like virus and paramyxovirus screening in Brazilian bats

Angélica Cristine Campos[1]; Luiz Gustavo Góes[1]; Cristiano Carvalho[2]; Guilherme Ambar[5]; Luciano M. Thomazelli[1]; Jhiovana Cristielly Costa[1]; Mariana Cristine de Souza[1]; Adriana Ruckert[3]; Débora C. Oliveira[3]; Luzia F. Martorelli[3]; Ana Paula Kataoka[3]; Marcelo S. Nardi[4]; Juliana L. Summa[4]; Roberta Marcatti de Azevedo[4]; Wagner A. Pedro[2]; Luzia H. Queiroz[2]; Ariovaldo P. Cruz-Neto[5] and Edison Durigon[1]

do Município de São Paulo, São Paulo-SP; [5] Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista (UNESP), Rio Claro-SP

Objectives: Bats are recognized as natural reservoirs of emergent viruses related to severe human disease outbreaks including Rabies, Nipah, Hendra and SARS coronavirus. Since the discovery of Hendra and Nipah emergent paramyxovirus in late 1990s in flying foxes bats from Australia and Asia, others bat-borne paramyxovirus have been identified in bats across the globe including bats species from Australia, Asia, Africa and America. Recently, new members of the influenza A virus where detected in bats from Guatemala and Peru, amplifying the host variety of Influenza virus A group. Despite the recent detection of Influenza-A and Paramyxovirus in South American bats and the spill-over events of paramyxovirus from bats to humans only few studies had analyzed the occurrence of influenza-like virus and paramyxovirus in Brazilian's bats. These study aims to analyze the occurrence and diversity of influenza-like virus and paramyxovirus in Brazilian bats. **Methods:** A total of 1071 samples including distinct tissues (intestine, lung, kidney and spleen), rectal and oral swabs, and serum (821 individuals/47 species) from urban area and Atlantic Forest biome were analyzed. The Total Nucleic Acid was extracted and cDNA synthesis was performed. Samples were screened by Pan-Flu PCR assay targeting the Influenza PB1 gene and by a Semi-Nested Pan-paramyxovirinae PCR assay targeting the L gene. **Results:** PCR fragments for both assays were observed in electrophoresis analysis. The amplicons were purified and sequenced by Sanger method. Sequencing confirmed the presence of 3 distinct Paramyxovirus lineages in eight bats. Morbillivirus-like was detected in insectivorous bat's *Molossus rufus* (intestine) and *Myotis nigricans* (lung)*;* Unclassified Paramyxovirus and one possible Henipa-like virus was found in hematophagous bats *Desmodus rotundus* in kidney samples*.* **Conclusions:** This study report the lack of detection of influenza-like in a high number of bat samples and may indicate the absence or the lower prevalence of these virus group in bats from Brazil. Our results also suggest the presence of paramyxovirus genotypes in bats commonly found in rural and urban area, including a probably Henipa-like virus in hematophagous bats, species that already had been described as vectors of rabies and others paramyxovirus with unknown zoonotic potential.

Hendra virus dynamics and spillover

Raina Plowright[1], Maureen Kessler[1], Alison Peel[2], Hamish McCallum[2], Peggy Eby[3]

[1]Department of Microbiology and Immunology, Montana State University; [2]Environmental Futures Research Institute, Griffith University, Queensland, Australia; [3]University of New South Wales, Australia.

Hendra virus provides a model system for understanding the dynamics of emerging bat viruses and spillover. One factor constraining our ability to study Hendra virus spillover is the limited knowledge of the biology of the virus within its reservoir hosts. We present three different hypotheses for how within-host pathogen dynamics in bats may interact with among host factors to drive dynamics of emerging bat virus spillover. These hypotheses include: pulsed viral excretion due to seasonal epidemics, local persistence due to waning immunity within bats, or episodic shedding from persistently infected bats. We discuss the evidence for each hypothesis and show that differentiation among these scenarios is essential for predicting and managing spillover.

Using serology to understand the dynamics of concurrent viral infections in pteropid bats

Jonathan H. Epstein[1], Noam Ross[1], Ariful Islam[1], Dan Crowley[1,2], Gary Crameri[3], Christopher Broder[4], Linfa Wang[5], and Peter Daszak[1].

[1]EcoHealth Alliance, NY USA; [2]Columbia University Mailman School of Public Health, NY USA; [3]CSIRO Australian Animal Health Laboratory, Geelong, VIC, AUS; [4]Uniformed Services University, MD USA; [5]Duke-NUS, Singapore

Objectives: Fruit bats of the genus *Pteropus* are reservoirs for henipaviruses throughout their range. *Pteropus medius* is the natural reservoir for Nipah virus in India and Bangladesh, and mechanisms of spillover to humans primarily involves contamination of date palm sap with excreta. Serological dynamics have provided insight into patterns of Nipah virus infection in this host, but other viruses, including Nipah-like viruses have been identified through pathogen discovery techniques. Little is known about infection patterns of other viruses within this species, or their likelihood of infecting other animals or people. **Methods**: We screened sera from a single population of *P. medius* in Bangladesh collected quarterly over six years for IgG antibodies against henipaviruses (NiV, HeV, CEDV), filoviruses (EBOV, MARV), and Menangle virus, using assays containing virus-specific solubilized glycoproteins or F proteins in a Luminex platform. **Results and Conclusions:** Here we present preliminary observations of comparative temporal patterns for multiple viral agents that suggest co-circulation in this population. We also discuss challenges in interpretation of serology

when studying viral infections in wildlife, particularly when multiple antigenically related viruses may be present.

Estimating viral richness and viral sharing in bats: integrating previously-published and newly-acquired field data

Kevin J. Olival[1], Noam Ross[1], Evan A. Eskew[1], Anna R. Willoughby[1], Carlos Zambrana-Torrelio[1], Peter Daszak[1], and PREDICT Consortium[2]

[1]EcoHealth Alliance, New York, NY 10001, USA; [2]http://www.vetmed.ucdavis.edu/ohi/predict/publications/Authorship.cfm

Objectives: A handful of studies published over the last 8 years have sought to identify the host, ecological, and evolutionary factors that best explain species-level differences in viral richness in bats. Similarly, a few studies have also aimed to answer the golden question: Do bats carry a significantly larger number of total viruses, or a larger number or proportion of zoonotic viruses than other mammals? Our objective is to address these critical questions using statistical models and large datasets collated from the literature and acquired from the field. **Methods:** We collated data from the past 75 years of published for over 2800 mammal-virus associations, representing 754 mammal species and 586 ICTV-named viral species. We fit a series of generalized additive models to these data to identify and examine the functional form of significant predictor variables for total and zoonotic viral richness. Using our best-fit models we also estimate expected viral richness for each host species under a scenario of 'maximum' research effort. We map these viruses in geographic space. We also use species accumulation curves to estimate viral richness from standardized, field-acquired data from the USAID PREDICT project (http://www.healthmap.org/predict/). Network models and statistics were used to compare patterns of viral sharing among bats between the literature and field-acquired datasets. **Results:** For the all mammal analyses: The best-fit model for total viral richness per wild mammal species explained 49.2% of the total deviance, and included a per-species measure of disease-related research effort, phylogenetically corrected body mass, geographic range, mammal sympatry, and taxonomy (order) After controlling for research effort, the proportion of zoonotic viruses per species is predicted by phylogenetic relatedness to humans, host taxonomy and human population within a species range—which may reflect human–wildlife contact. We demonstrate that bats harbor a significantly higher proportion of zoonotic viruses than all other mammalian orders. For the bat field-acquired data we show significant differences in viral richness estimates across bat genera and viral family, as well as differences in the rates of saturation. Clustering in bat host-virus networks follow some predictable patterns and identify additional bat species to target for viruses of interest. **Conclusions:** These host-specific analyses and estimates of viral richness, including the unobserved or 'missing' viruses, allow us to better identify and target which species and regions should be preferentially targeted to characterize the global bat virome.

Optimised sampling efforts and screening assays identify several MERS-related coronaviruses in South African bats

Wolfgang Preiser[1,2], Ndapewa L. Ithete[1], Nadine Cronjé[1], Tasnim Suliman[1]

[1] Division of Medical Virology, Faculty of Medicine & Health Sciences, University of Stellenbosch, South Africa; [2] National Health Laboratory Service (NHLS) Tygerberg, Cape Town, South Africa

Objectives: Bats are considered reservoir hosts for all mammalian alpha- and beta-coronaviruses (α-, β-CoV). Following the emergence of SARS in 2002/03 and the subsequent identification of *Rhinolophus sinicus* as the likely ancestral SARS-CoV source, a wide diversity of bat CoV has been described worldwide. We work in transdisciplinary collaborations with ecologists and zoologists to define CoV diversity and ecology in South African bats. In addition to general "opportunistic" surveillance, species-specific studies of *Neoromicia capensis* and *Rhinolophus spp* are conducted, including longitudinal studies of bat colonies to determine shedding patterns and diversity of viruses present. **Methods:** Since 2011, 24 different bat species have been sampled along rainfall and altitudinal gradients across different biomes; namely Fynbos, Forest, Nama Karoo, Grassland, and Savanna. Sample types include faecal pellets, saliva and urine swabs, and when voucher specimens are sacrificed for museum collections, also blood and organs. Sequences of the 816bp RGU fragment (Drexler et al., 2010) for species classification were used to construct ML trees in MEGA v7. **Results:** An improved screening method greatly increased the CoV detection rate. Of 686 samples tested, 92 from 9 bat species were screening-positive: 66 for α-CoV, 19 for β-CoV, and 7 for both. The majority of sequences identified are α-CoVs, with ~20% prevalence for *N. capensis*. Preliminary analyses of partial RdRp, nucleocapsid and spike gene fragments of novel β-CoV identified in Neoromicia and Pipistrellus bats are closely related to BtCoV PML-PHE1/RSA/2011 (NeoCoV), previously found by us in a *N. capensis* and belonging to the same viral species as the recently emerged MERS-CoV, responsible for the ongoing

outbreak in the Arabian Peninsula. **Conclusions:** Extensive, dedicated sampling efforts allowed detection of α- and β-CoV from a wide range of bat species across large parts and different biomes of South Africa. An improved screening PCR approach yielded significantly more positive samples. There is substantial CoV diversity in southern African bats, including, most importantly, additional MERS-CoV-related CoV, which will hopefully help to address the unresolved question of the origin of this zoonotic pathogen.

Coronavirus diversity in bats from urban, rural and forest areas of Atlantic and Amazon Forest biomes, Brazil.

Luiz Gustavo Góes[1]; Angélica Cristine Campos[1]; Cristiano Carvalho[2]; Guilherme Ambar[5]; Douglas Oliveira[1]; Caroline Alvarenga[1]; Jhiovana Cristielly Costa[1]; Adriana Ruckert[3]; Débora C. Oliveira[3]; Luzia F. Martorelli[3]; Ana Paula Kataoka[3]; Marcelo S. Nardi[4]; Juliana L. Summa[4]; Roberta Marcatti de Azevedo[4]; Luzia H. Queiroz[2]; Ariovaldo P. Cruz-Neto[5] and Edison Durigon[1]

[1] Departamento de Microbiologia, Instituto de Ciências Biomédicas (ICB), Universidade de São Paulo (USP), São Paulo-SP; [2] Faculdade de Medicina Veterinária de Araçatuba, Universidade Estadual Paulista (UNESP), Araçatuba- SP; [3] Centro de Controle de Zoonozes (CCZ) do Município de São Paulo-SP; [4] Divisão Técnica de Medicina Veterinária e Manejo da Fauna Silvestre (DEPAVE-3), Secretaria do Verde e Meio Ambiente, Prefeitura do Município de São Paulo, São Paulo-SP; [5] Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista (UNESP), Rio Claro-SP

Objectives: Epidemiological and phylogenetic studies indicate that four out of six coronavirus capable of infecting humans are the result of spill over events of virus from bats to humans. Despite the great diversity of coronaviruses in bats, the large number of bat species in Brazil (15% of the world's bat diversity) and the presence regions classified as hotspot for zoonotic pathogen emergence only few studies have analyzed the circulation of coronaviruses in Brazilian's bats. This study aims to evaluate the diversity of CoV circulating in bats in Brazil, covering different species, habitats, and life history of the hosts. **Methods:** We analyzed 840 bats from 53 species and five bat families with a pancoronavirus detection assay. Intestine, lungs, serum and rectal/oral swabs were obtained from bats from forest, urban, and rural areas located in the Atlantic and Amazon Forest biomes. **Results:** Distinct coronavirus lineages were detected in in bats from all sites screened. The coronavirus RNA was detected in 27 individuals from eleven bat species including *Artibeus lituratus(4), Carollia perspicillata (5), Eumops glaucinus(1), Glossophaga soricina (3), Mimon crenulatum(1), Molossus rufus(2), Molossus molossus (1), Myotis nigricans(1), Myotis riparus (1), Phyllostomus discolor(1)* and *Sturnira lilium (7)*. The analysis of coronavirus phylogenetic relation from nucleotide sequences obtained showed the circulation of the 25 Alphacoronavirus genotypes (α-CoV) and two Betacoronavírus (β-CoV), distributed in thirteen lineages (eleven α-CoV and two β-CoV). Results indicate the presence of a great coronavirus diversity in bats from Brazil including potential new and already described lineages. We describe the detection of a bat coronavirus genetically related with Alphacoronavirus-1 species, which are a group of closely related viruses with an evolutionary history of recombination and cross-species transmission between domestic and livestock animals. We also report the circulation of Betacoronavirus lineage "C", related to emergent highly pathogenic coronavirus CoV-MERS, in South American bats commonly found in urban areas, representing the first detection of coronavirus Clade C in this subcontinent. **Conclusions:** Our report points to the great diversity of CoV genotypes in New World bats, more specifically in the Atlantic Forest Biome, providing a better understanding of CoV diversity, host range and biogeographic distribution.

Preliminary Evidence of a Novel Alphacoronavirus and Secondary Acquisition of Tymoviridae and Partitiviridae in Little Brown Bats (*Myotis lucifugus*) in Southcentral Alaska.

Douglas Causey[1], Jonathan C. Rupp*[1], Maegan Lange[1], Megan Howard[2], Anitha Sundarajan[3], Jonny Sena[3], Faye D. Schilkey[3], Molly Murphy[4], Sarah Cooperman[1], Eric Bortz[1]

[1]Dept. of Biological Sciences, University of Alaska Anchorage; [2]Battelle Memorial Institute; [3]National Center for Genome Resources, Santa Fe NM; [4]Dept. of Veterinary Medicine, University of Alaska Fairbanks
*Presenter

Objective: We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus*, the little brown bat. Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. **Methods**: Total RNA extracts were screened by RT-PCR and CoV ORF1a, and primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. **Results**: Sanger sequencing of amplicons confirmed the presence of an alpha-coronavirus phylogenetically related to

persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. Aligning to a reference *M. lucifigus* virus from Colorado, bat alphacoronavirus CDPHE15/USA/2006, we assembled a full-length genome (28,515nt) identifying the novel alphacoronavirus/bat/Alaska/s7/2014. A high degree of thermodynamically stable stem-loop RNA structures are predicted by Mfold within 700nt of 5' and 3' termini of genome**.** While nucleotide conservation to the Colorado virus was 96%, notable amino acid differences were identified in coronavirus proteins. In two distinct bat samples, preliminary results indicate the likely presence of tymovirus (eg. Dulcama mottle virus) probably acquired through ingestion of insects feeding on infected plants. In addition, initial results indicate presence of alpha-partitivirus closely aligned to *Rosellina*-type associated with spruce/alder and other partitivirus-like sequences. Secondary acquisition of virus obtained by feeding or incidental infection by fungi (eg. gamma-partitivirus associated with *P. destructans*) has been previously described for bats collected from similar ecological settings (eg. Thapa et al. 2016). **Conclusions**: We continue to further refine these initial for better resolution of the virome of Alaska bats.

Are big brown bat cells different than human cells in their innate immune response to coronavirus and viral ligands?

Arinjay Banerjee[1], Robert Brownlie[3], Noreen Rapin[1], Trent Bollinger[2], Darryl Falzarano[1,3] and Vikram Misra[1]

[1]Department of Microbiology, Western College of Veterinary Medicine, University of Saskatchewan, Canada. [2]Department of Pathology, Western College of Veterinary Medicine, University of Saskatchewan, Canada. [3]VIDO-InterVac, University of Saskatchewan, Canada.

Objectives: Bats are hosts for viruses such as those that closely resemble coronaviruses (CoV) that cause severe acute respiratory syndrome (SARS), Middle East respiratory syndrome (MERS) and porcine epidemic diarrhoea (PED). Despite the serious nature of these diseases in other mammalian hosts, bats naturally infected with CoV or experimentally infected with MERS-CoV do not demonstrate clinical signs of disease. We challenged big brown bat (*Eptesicus fuscus*) cells and human cells with MERS-CoV or viral ligands to study the differences in their interferon and inflammatory responses. **Methods:** *E. fuscus* kidney cell line and bone marrow derived cells, human fibroblast and epithelial cells were challenged with either MERS-CoV or poly(I:C), a double stranded RNA surrogate. Transcripts for several innate immune response genes were quantified using qRT-PCR. Interaction between the bat TNF promoter and a potential repressor of the promoter, c-Rel, was detected by chromatin co-immunoprecipitation and bat c-Rel, TLR3, RIGI and MDA5 transcripts were knocked-down using specific siRNA. **Results:** Both human and bat cells, when stimulated with poly(I:C), contained higher levels of transcripts for interferon beta than unstimulated cells. In contrast, only human cells expressed robust amount of RNA for TNFα, a cell signaling protein involved in systemic inflammation. We further observed that poly(I:C) signaled primarily through TLR3 in big brown bat cells. We examined the bat TNFα promoter and found a potential repressor (c-Rel) binding motif. We demonstrated that c-Rel binds to the putative c-Rel motif in the promoter and knocking down c-Rel transcripts significantly increased basal levels of TNFα transcripts. Both human and bat cells support replication of MERS-CoV to comparable levels. **Conclusions:** We have identified a novel transcription repressor, c-Rel, that inhibits an increase in TNFα transcripts in bat cells after poly(I:C) stimulation. We have also showed for the first time that poly(I:C) signals through TLR3 in bat cells. We are currently studying the modulation of the innate immune response in bat cells by MERS-CoV and individual MERS-CoV and bat coronavirus proteins. Identifying adaptations in the bat innate immune response might allow us to extrapolate the knowledge in identifying potential drug targets in spill-over species, such as humans.

Reverse genetic analysis of bat influenza viruses: A journey full of surprises.

Martin Schwemmle, Institute of Virology, University of Freiburg Medical Center

Our understanding of conventional influenza A viruses was recently challenged by the identification of two novel genome sequences of influenza A-like viruses from bat specimens by next-generation sequencing. Serological surveys indicate that these viruses circulate in various bat species in Central and South America. However, no viable viruses could be isolated from bats, impeding further characterization of these viruses. Interestingly, analysis of the viral surface proteins revealed that the entry machinery of these viruses differ significantly from all known conventional influenza A viruses and may only support entry into bat cells. This talk will summarize recent progress obtained by reverse genetic analysis of bat influenza A-like viruses, including the observation that the host tropisms of these viruses might be larger than anticipated.

Towards understanding bat influenza A-like viruses

Wenjun Ma[1], Bin Zhou[2], Jingjiao Ma[1], Qingfang Liu[1], Jinhwa Lee[1], Michael Duff[1], Juergen A. Richt[1], David E. Wentworth[2]

[1]Department of Diagnostic Medicine/Pathobiology, College of Veterinary Medicine, Kansas State University, Manhattan, Kansas, United States of America.

[2]Virology, J. Craig Venter Institute, Rockville, Maryland, United States of America.

Objectives: Bats harbor many viruses, which are periodically transmitted to humans resulting in outbreaks of disease (e.g., Ebola, SARS-CoV). Recently, bat influenza A-like virus HL17NL10 and HL18NL11 sequences were identified; however, no viruses were isolated from bats. This discovery aroused great interest in understanding the evolutionary history and pandemic potential of bat-influenza virus. **Methods**: Using synthetic genomics, we rescued a modified bat-influenza virus that had the HA and NA coding regions replaced with those of A/PR/8/1934 (H1N1). **Results**: This modified bat-influenza virus replicated efficiently in vitro and in mice, resulting in severe disease. The results indicate that internal genes of bat influenza A-like viruses are functional to support virial genome transcription and virus replication. Mini-genome replication studies and virus reassortment experiments demonstrated that bat influenza A-like virus has very limited genetic and protein compatibility with Type A or Type B influenza viruses, yet it readily reassorts with another divergent bat influenza A-like virus. **Conclusions**: In conclusion, our data indicate that the bat influenza A-like viruses recently identified are authentic viruses that pose little, if any, pandemic threat to humans; however, they provide new insights into the evolution and basic biology of influenza viruses.

Experimental Infection of Jamaican Fruit Bats (*Artibeus jamaicensis*) with a Rescued Bat HL18NL11 Influenza A-like Virus

Tony Schountz[1], Ashley Malmlov[1], Jingjiao Ma[2], Jinhwa Lee[2], Corey Campbell[1], Tawfik Aboellail[1], Ann Hawkinson[3] and Wenjun Ma[2]

[1]Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University; [2]Department of Diagnostic Medicine and Pathobiology, College of Veterinary Medicine, Kansas State University; [3]School of Biological Sciences, University of Northern Colorado

Objectives: Nucleotide sequences of two novel influenza A-like viruses, HL17NL10 and HL18NL11, were recently discovered in New World little yellow shouldered fruit bats (*Sturnira lilium*) and flat-faced fruit bats (*Artibeus planirostris*), respectively. Serological studies indicated high prevalence to these viruses among many species of Phyllostomidae leaf-nosed fruit bats of Central and South America, including Jamaican fruit bats (*Artibeus jamaicensis*). **Methods**: Infectious viruses have not been isolated from bats, therefore an infectious clone of HL18NL11 was generated by reverse genetics technologies that produced particles resembling influenza viruses from transfected cells by electron microscopy. Susceptibility of Jamaican fruit bats to rescued HL18NL11 bat influenza A-like virus was determined during a 28-day challenge experiment via intranasal inoculation. **Results**: The bats exhibited no overt clinical signs of disease nor fever. However, rectal swabs had up to 10^4 $TCID_{50}$ equivalents of HL18NL11 vRNA by real-time PCR in each bat on days 2, 4 and 7 post inoculation, but not day 15 or 28, and in the lungs of one of the bats on day 28 when they were euthanized. Serology showed moderate antibody titers to nucleoprotein by ELISA. Histopathology revealed mild pathology, particularly in the one bat with detectable vRNA in its lung. This bat's lungs showed multifocal mild-to-moderate histiocytic and lymphoplamacytic interstitial pneumonia. Pleocellular infiltrates were especially prominent around adventitia of pulmonary arterioles. Immunohistochemistry with mouse antibody to recombinant H18N11 nucleoprotein revealed virus antigen in the lungs of this bat. **Conclusions**: This is the first study to demonstrate susceptibility to bat influenza viruses and suggests that viral persistence up to 28 days may occur in some bats, supporting the hypothesis that Jamaican fruit bats may be a natural reservoir host of the HL18NL11 virus.

Seroprevalence of alphaviruses, flaviviruses and Rift Valley fever virus in Ugandan bats

Kading RC[1,2], Kityo R[3], Mossel E[1], Borland E[1], Nakayiki T[4], Nalikka B[3], Nyakarahuka L[4], Ledermann J[1], Panella N[1], Gilbert A[5,6], Crabtree M[1], Kerbis Peterhans J[7], Towner J[8], Amman B[8], Sealy T[8], Nichol S[8], Powers A[1], Lutwama J[4], Miller B[1]

[1]Centers for Disease Control and Prevention, Division of Vector-borne Diseases, Arbovirus Diseases Branch, Fort Collins, CO; [2]Current Affiliation: Colorado State University, Department of Microbiology, Immunology and Pathology, Fort Collins, CO; [3]Makerere University, Department of Biological Sciences, Kampala, Uganda; [4]Uganda Virus Research Institute, Entebbe, Uganda; [5]Centers for Disease Control and Prevention, Division of High Consequence Pathogens, Rabies and Poxvirus Branch, Atlanta, GA; [6]Current Affiliation: United States Department of Agriculture, Animal and Plant Health Inspection Service, Fort Collins, CO; [7]College of Professional Studies, Roosevelt University &Collections & Research, The Field Museum of Natural History, Chicago, IL;

[8]Centers for Disease Control and Prevention, Division of High Consequence Pathogens, Viral Special Pathogens Branch

Objectives: Arboviruses including Rift Valley fever virus (RVFV), chikungunya virus (CHIKV) and Sindbis viruses have previously been isolated from naturally-infected East African bats, however the role of bats in arbovirus transmission cycles is poorly understood. The aim of this study was to investigate the exposure history of Ugandan bats to a panel of arboviruses. **Methods**: Insectivorous and fruit bats were captured from multiple locations throughout Uganda between 2009 – 2013. All bat captures were conducted under the approval of IACUC protocols 1731AMMULX (Maramagambo samples) and 010-015 (all other samples). Bats were captured using harp traps or mist nets, taking appropriate biosafety precautions. All serum samples were frozen at -80°C until they were tested for neutralizing antibodies against West Nile virus (WNV), yellow fever virus (YFV), Dengue 2 virus (DENV-2), Zika virus (ZIKAV), CHIKV, o'nyong-nyong virus (ONNV), Babanki virus (BABV), and RVFV by plaque reduction neutralization test (PRNT). **Results**: Sera from up to 626 bats were screened for neutralizing antibodies against each virus. Key findings include the presence of antibodies against ONNV in approximately 15% (44/303) of Egyptian rousette bats (*Rousettus aegyptiacus*) from Maramagambo forest in western Uganda, and antibodies against RVFV in Ethiopian epauletted fruit bats (*Epomophorus labiatus*) captured from Kawuku (5/52) and Egyptian rousette bats from Kasokero cave (3/54). **Conclusions**: Antibodies reactive to flaviviruses were widespread across bat taxa and sampling locations.The data presented demonstrate the widespread exposure of bats in Uganda to arboviruses, and highlight particular virus-bat associations that warrant further investigation.

Presence of zoonotic bat pathogens correlate with reproductive seasons in South African bat populations
Wanda Markotter[1], Muriel Dietrich[1], Teresa Kearney[2,3], Stewart McCulloch[1], Marinda Mortlock[1], Ernest Seamark[4,5] and Janusz Paweska[6]

[1] Centre for Viral Zoonoses, Department of Medical Virology, Faculty of Health Sciences, University of Pretoria, South Africa; [2] Ditsong National Museum of Natural History, Pretoria, South Africa.; [3] Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa; [4] AfricanBats, Kloofsig, South Africa. [5] Centre for Wildlife Management, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, South Africa; [6] Centre for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, South Africa.

In 2003 we initiated passive surveillance on bats in South Africa with the initial objective to identify rabies–related lyssaviruses, but this has since expanded to include several other possible zoonotic viral and bacterial pathogens. The project has identified viruses in the following families; *Rhabdo, Paramyxo, Bunya, Filo*, *Adeno-, Herpes-, Picorna, Orthomyxo, Circo, Parvo, Papilloma* and *Coronaviridae* as well as the following bacterial pathogens; *Leptospira*, *Rickettsia and Bartonella.* **Objectives:** To determine longitudinal circulation of pathogens we initiated seasonal sampling from 2012 in two cave systems in South Africa. This sampling specifically focused on the reproductive seasons of *Rousettus aegyptiacus* and *Miniopterus natalensis*. **Methods:** Serum was analysed for rabies related lyssavirus, Lagos bat virus, antibodies using a virus neutralization assays. Tissue, urine saliva and fecal samples were tested for the presence of viral nucleic acids using RT-PCR/PCR specific for several viral families. Illumina MiSeq 16S rRNA gene sequencing on low-biomass individual bat samples was used to identify bacterial pathogens. **Results:** Longitudinal studies, specifically focused on measuring the presence of LBV antibodies in *Rousettus aegyptiacus*, indicated cyclic fluctuation of antibodies with a marked increase shortly after the parturition period, which identified this as a high risk period for spill-over. We showed that seasonal bat reproduction is a major driver shaping temporal variations in microbial community structure. A strong temporal shift in oral, fecal and urinary microbiota was also associated with bat reproduction, with significant associations between the microbiota and the sex, or reproductive status. **Conclusion**: This cumulative evidence can be used to indicate periods of increased viral and bacterial circulation, which can be used to make public and veterinary health decisions on spill-over risks.

Body mass index of the Egyptian fruit bat, *Rousettus aegyptiacus*: An indicator of infection status
Low J. de Vries, [1], Stewart McCulloch[1], Janusz Paweska[2] and Wanda Markotter[1]

[1] Centre for Viral Zoonoses, Department of Medical Virology, Faculty for Health Science, University of Pretoria, South Africa; [2] Center for Emerging, Zoonotic and Parasitic Diseases, National Institute for Communicable Diseases, Sandringham, Johannesburg, South Africa

Body mass in conjunction with forearm length has long been used to determine body mass indices for bats. These indices have been further linked to diseases detected in bats, with a low body mass index being a potential indicator of infected bats. **Objectives**: We correlated body measurements to body mass, enabling us to determine

the best measurement that could be used to build body mass indices which can be correlated to disease status of *Rousettus aegyptiacus.* **Methods**: This study focuses on the Egyptian fruit bat (*Rousettus aegyptiacus*) in the Limpopo Province of South Africa. Data was gathered over a two year period, 2015 and 2016, and consisted of measurements of various body parts. **Results**: Wilcoxon Matched pair tests indicated a significant difference in body weight between the two sampling years (V = 34476, p = 0.002466). A strong correlation was found between body mass and forearm length when both years are considered (S = 17252000, p-value < 2.2e-16), as well as for the first (S = 3487900, p-value < 2.2e-16) and second year (S = 1250500, p-value < 2.2e-16) of the study with a strong correlation value; R > 0.78 in all cases. The correlation between mass and forearm length was significant for both males and females during both years (p-value < 2.2e-16), but the correlation value was always lower for females. Other body measurements correlated significantly with body mass, but only forearm length showed a strong correlation. **Discussion**: Forearm length is thus an indicator of body mass in Egyptian fruit bats, as has been found for insectivorous bats. As such, body mass in conjunction with forearm length could be used to build body mass indices, which could be used as a preliminary indicator of disease status for *Rousettus aegyptiacus.*

Environmental constraints drive the viral diversity of two sympatric Amazonian bat species
Arielle Salmier, Sourakhata Tirera, Benoit de Thoisy, Alain Franc, Edith Darcissac, Damien Donato, Christiane Bouchier, Vincent Lacoste and Anne Lavergne

Institut Pasteur de la Guyane

Amazonia is a major biodiversity hotspot which encompasses a great diversity of bat species, as well as a wide variety of climates and vegetation formations. Landscape characteristics (*e.g*. climate, vegetation structure, anthropogenic disturbances) are relevant predictors of species richness and influence the host-pathogens relationships. However, the effects of contrasting environmental conditions on the viral diversity harbored by Amazonian bats have yet to be investigated. Through a metagenomic approach we characterized the viral diversity of two sympatric Amazonian bat species: the common vampire bat, *Desmodus rotundus* (*Phyllostomidae*) and the insectivorous bat, *Molossus molossus* (*Molossidae*). Then, through a statistical approach, we assessed the impact of the landscape characteristics by comparing the viral richness harbored by different populations of vampires and insectivorous bats inhabiting different environments (*e.g.*, forests, edge habitats, anthropized and urban areas). We identified 10,983 viral sequences related to 48 viral families known to infect a wide range of hosts (*i.e.*, bacteria, plants, insects and vertebrates). Most viruses detected reflect the dietary habits, especially within the insectivorous bat species which presented the highest diversity of plant and insect-related viral families. Diversity tests and phylogenetic relationships reconstructed for several mammal-related viral families (*e.g.*, *Bunyaviridae*, *Circoviridae*, *Foamyviridae*, *Herpesviridae*, *Papillomaviridae*) revealed a preferential transmission route within phyla of bats, as well as a potential association of viral diversity with the host's gut microbiota. Three structuring poles related to species traits and environments were identified, explaining the distribution of viral diversity and showed a strong correlation between the type of environment, host phylogeny, diet and viral diversity. The substantial viral richness detected in forest environments is likely due to a wider diversity of prey and favored by more frequent contacts between hosts and overlapping habitats. These findings provide significant insight into viral bat diversity in Amazonia and emphasize that environmental constraints and host features are the main drivers of viral diversity in bat species.

Seasonal and individual predictors of grey-headed flying fox (*Pteropus poliocephalus*) foraging movements in Adelaide, South Australia
Cecilia A. Sánchez[1,2], Terry B. Reardon[3], Wayne S.J. Boardman[4] and Sonia Altizer[1,2]

[1]Odum School of Ecology, University of Georgia, Athens, GA, USA; [2]Center for the Ecology of Infectious Diseases, University of Georgia, Athens, GA, USA; [3]South Australian Museum, Adelaide, South Australia, Australia; [4]University of Adelaide, Adelaide, South Australia, Australia

Objectives: The distribution of flying foxes in Australia is influenced by the unpredictable availability of their preferred diet, especially eucalypt blossoms. Recently, human activities, including destruction of native habitat and planting of non-native vegetation that provides predictable foraging, have altered the distribution and movements of flying foxes. The consequences of this change are important for both bat and human health, given that bats are reservoirs of Australian bat lyssavirus and Hendra virus, both of which cause fatal disease in humans. In 2010, grey-headed flying foxes (*Pteropus poliocephalus)* established a permanent roost in Adelaide, South Australia, several hundred kilometers outside their previous range. Despite incurring juvenile mortality due to extreme heat events, the population now numbers approximately 7000 and is expected to continue growing. **Methods:** As part of a larger study to characterize the health and behavior of the Adelaide flying fox population, we deployed lightweight GPS loggers on bats to track their foraging movements. Loggers recorded a bat's position every 30 seconds when flying and every 45 minutes when stationary, and also recorded acceleration,

speed, and altitude data. Forty foraging sites were ground-truthed to identify feeding resources. **Results:** Five flying foxes were tracked in winter 2016 and 9 in summer 2017, resulting in 112 nights of movement data. Bats exhibited individual variation in movement patterns, with some foraging repetitively, and others ranging more widely over the landscape. The nightly distance traveled depended on the interaction between sex and the ratio of weight to forearm length, but not on season. In the summer, bats foraged predominantly on urban resources, with figs and eucalypts being especially popular. **Conclusions:** This work provides insight into a recently-established, understudied bat population and is useful both to local Adelaide stakeholders as well as other urban citizens seeking to manage the bats that share their space. Foraging on urban resources, especially in residential yards, could increase the chances for disease transmission from flying foxes to humans and pets. Individual predictors of movement should be considered when building models of bat movement and disease risk.

Uganda Bat calls library-developing a tool to survey arthropod-borne viruses associated with Chiroptera
Kityo Robert Martin[1], Kading Rebekah[2], Nalikka Betty[1], Lutwama Julius[3]
[1]Makerere University, College of Natural Science – Department of Zoology, Entomology and Fisheries Science Kampala Uganda; [2]Colorado State University; [3]Uganda Virus research institute

Objectives: We continue to conduct studies of bats in different parts and habitats of Uganda with a number of particular goals: -

i. To continue to understand the occurrence and ecology of bats that may be reservoirs and/or vectors of viruses in Uganda (BM presentation),
ii. To develop a micro-chiroptera calls Library for the country
iii. Continue the development a fast approach that can be used to quickly survey and identify the bat fauna of different parts of Uganda.
iv. To investigate the roles of different species of bats in the ecology of viruses (RK presentation),

Methods: Through a DTRA supported project we particularly targeted to understand bat ecology and their potential roles in virus ecology. This was done through graduate training and research, training in field techniques of capture and processing of bats for detection of and characterization of viruses a pillar institutional players and a compilation of reference calls of micro-chiropteran bats for Uganda. Field biosurveillance training was held with participants from NADDEC, UVRI and Makerere University at Zika forest. A graduate student now preparing his dissertation, was recruited and completed an ecological study on bats in the Kaptum cave. Insect bats are captured using Mist nets, Herp traps and Hand net capture at roost sites. Bats are either free flown, ziplined or light tagged and hand released from which voucher calls are collected. Collected calls are processed using Kaleidoscope Pro version 31.7 for large files that need to be split for examination and processing in Sonobat4.0.6p. **Results**: Cumulatively, voucher calls for 50 species of micro chiropteran bats (over 50% of the Ugandan species) have been collected. Several of these are represented by multiple bats that way taking care of potential intra specific variations, potential ecological variations each of which could affect the call produced by the species. This presentation specifically shares our findings on call characteristics for a sample of the species and highlights the great overlap in signatures for species of Molosid bats, species of the Genus *Scotophilus*, while showing very nicely segregated call signals for Hipposiderid, Rhinolophid and a good number of verspertilionid bats. **Conclusions**: Our next steps are to attempt to collect voucher calls from species we haven't, collect additional calls from species already recorded but from few individuals, and to work with partners to develop a tool that could be used to rapidly identify calls collected from bat detection surveys from different parts of the country.

Dampening of STING-dependent IFN production: an implication of virus tolerance in bats?
Jiazhen Xie[1], Chenxi Ma [1], Yang Li[1], Jie Cui[1], Linfa Wang [2], Zhengli Shi [1] and Peng Zhou[1*]

[1]Wuhan Institute of Virology, Chinese Academy of Sciences, Wuhan 430071, China; [2]Emerging Infectious programme, Singapore Duke-NUD Medical School, Singapore 169857, Singapore

Objectives: Bats are known to harbour a number of zoonotic viruses, many of which are highly pathogenic in human but result in no clinical symptoms in bats. The mechanism of how bats coexist with viruses is still largely unknown. We previously reported the contraction of type I IFN locus and unusual constitutively expression of IFNA in bats. We hypothesis this may help bat to inhibit virus replication. However, as immune response can also do harm to the host, then how bats tolerate viruses and viral induced immune responses become a question. **Methods:** To address this question, we scanned a list of DNA and RNA sensors in bats. We then focus on STING, which played a key role in multiple DNA sensing pathways, for understanding how bats tolerate DNA viruses. We also tested the functionality of bat STING in a list bat immune or non-immune cells. **Results and Conclusions:** We found some of the viral DNA sensors are under faster evolution, implying a change of function. Further experimental data also confirmed the dampening of viral DNA sensing, more specifically STING- dependent IFN production pathway. We then identified a ubiquitous key point mutation in all bat species tested, which hugely

decreased the cGAS-STING sensing ability (80%) by gain-of-function studies. Lastly, we restored the functionality of STING and STING-dependent viral DNA sensing pathway by changing this site to human. We conclude that bat naturally own a dampened STING-dependent IFN production, probably to avoid over responses to virus. This observation provides a model of how bats tolerance thus long-term hosting these viruses.

Regulation of immune activation and dampened inflammation in Pteropid bats
Aaron T. Irving[1], Katarina Luko[1], Matae Ahn[1], Kong Pui San[1], & Lin-Fa Wang[1]

[1]Duke-NUS Medical School, Singapore

Objective: Natural reservoir hosts can maintain low-level infection of pathogens without succumbing to severe disease. Several bat species host viruses such as Ebola, SARS, Nipah, Hendra, and other pathogenic viruses and while these same infections cause mass-inflammation in humans and other animals they are mostly asymptomatic in the bat. As such, bats are a unique model for studying the host control of systemic inflammation. **Methods:** We utilised bat cell lines, primary cells and tissue with qPCR, Western Blot, FACS analysis, NGS transcriptomics and cellular proteomics to profile pathways and characterise signalling mechanisms. **Results:** Through studying immune activation to flaviviruses, influenza and reovirus, along with natural stimulants of innate immunity such as TLR and RLR ligands we are beginning to characterize key differences to their human counterparts for PRRs.. There appears to be differences also in the kinetics and activation signals required for Interferon activation also. In addition, our data, from investigation of primary bat immune cells and studying bat homologs, suggests that inflammasome activation pathways may be altered with dampened activation of downstream inflammation. **Conclusion:** Along with fundamental differences to cell biology, this may indicate an evolutionary adaptation that while supporting flight, may cause susceptibility to infection yet maintain a symbiotic state with several pathogens. Initial observations show several key mutations, altered kinetics and a decrease in sensitivity to induce signaling all appear to be involved. From this we can gain understanding into a mechanism for controlling excess inflammation in humans.

Delineating the phenotype and function of the B cell population in the fruit-eating bat, Pteropus Alecto.
Periasamy P.[1,2], Martínez Gómez J.M.[1,2], Wang LF[3] , and Alonso S.[1,2]
[1]Department of Microbiology and Immunology, [2]Immunology Programme, Yong Loo Lin School of Medicine, Life Sciences Institute, National University of Singapore, Singapore. [3]DUKE-NUS, Singapore.

Objective: The unique ability of bats to act as reservoir for viruses that are highly pathogenic to humans suggests unique properties and functional characteristics of their immune system. However, the lack of bat specific reagents, in particular antibodies, has limited our knowledge of bat's immunity.
Methods: Here, using cross-reactive antibodies, we report the phenotypic and functional characterization of B cells based on anti-mouse I-Ab (MHC-II) and anti-bat IgG. **Results**: Using flow cytometry, we show their distribution amongst the major lymphoid organs and scanned electron micrographs of these sorted population reveal that they are morphologically similar to human and murine B cells. In addition, a large population of these cells test positive for CD19 mRNA, tested using SmartFlare RNA probes, and anti-human CD19 antibody. Uniquely, these cells are able to show an increase in calcium uptake upon cross-linking of their B cell receptor with the addition of secondary donkey anti-goat antibody, which is specific for the goat anti-bat IgG. We also demonstrate T cells and myeloid cells do not release calcium in the presence of IgG and secondary antibody. Furthermore, we also demonstrate that injecting LPS for 5 hrs show an increase in MHC-II$^+$IgG$^+$ B cell population in the spleen and blood. This demonstrates a T-independent B cell activation amongst the B cell population. In addition, this population of cells do not respond to Poly (I:C) stimulation. We also performed single cell RNA sequencing on sorted MHC-II$^+$IgG$^+$CD19$^+$ positive cells to identify various B cell subsets based on their gene signature. Initial analysis reveal that these cells show increased expression of CD19 and do not express CD3, CD8 and CD11b. **Conclusions**: Here, we demonstrate for the first time the phenotype and function of B cells in *Pteropus Alecto.* This provides us with a platform to isolate and further elucidate the role of these cells in infectious models.

Integrative measures for assessing "health" in free-ranging bats – zoonotic and conservation implications from a One Health perspective

DeeAnn M. Reeder[1], Kenneth A. Field[1]

[1]Department of Biology, Bucknell University

Objectives: Risks of zoonotic spillover are likely related to the overall health of the animal host. For bat hosts of viral zoonotic diseases, the relationship between health and spillover risk is complex, with poor health possibly favoring transmission by increasing viral load and shedding but also decreasing animal mobility and human-host contact. Unfortunately, determining the health status of free-ranging bats is fraught with difficulty. Challenges exist not only in deciding which diagnostic measures to use, but also in interpreting the results of these measures. Furthermore, without the ability to measure fitness in these long-lived mammals, our understanding of the consequences of "good" or "bad" health for a free-ranging bat is poor. Our objective is to provide a framework for defining bat health that will facilitate bat studies and will enhance our understanding of spillover risk, ecosystem health, and human health. **Methods:** We combined an extensive literature review of health metrics in free-range wildlife, including bats, with our own long-term field studies and experiences studying bat physiology and disease. **Results:** Literature review and our past work point to several findings: (1) a number of measures commonly used in other vertebrate taxa and in other mammals have not been fully deployed for bats – sometimes owing to methodological hurdles; (2) due to a lack of tools, and often small sample volumes, most bat studies have relied on too-few measures, such as BMI (which suffers from allometric problems and is often surprisingly uninformative), the ubiquitous neutrophil-to-lymphocyte (N/L) ratio, ectoparasite load, and highly variable immune metrics such as hemmaglutination assays; (3) newer molecular methods, such as transcriptomic approaches hold promise for improving our understanding of bat health, especially when integrated with other measures such as infection status. We will present preliminary data from our recent field studies of African fruit bats in which we have deployed 20+ field diagnostic measures in combination with infection status and a transcriptomic approach. **Conclusions:** We recommend the development of integrative health metric(s), which will allow for the determination of the most informative measures for future studies. We also implore researchers to document normative physiological measures for more species of bats, analyzed with regards to life history, ecology, and phylogeny.

Host-pathogen interactions during white-nose syndrome

Ken Field[a], Sophia M Reeder[a], Jonathan M Palmer[b], Brent J Sewall[c], Jenni M Prokkola[d], Greg Turner[e], Thomas M Lilley[f], Marianne Gagnon[c], J Paul White[g], Joseph Johnson[h], Christopher Hauer[c], and DeeAnn M Reeder[a]

[a]Department of Biology, Bucknell University, Lewisburg, PA; [b]Center for Forest Mycology Research, Northern Research Station, US Forest Service, Madison, WI; [c]Department of Biology, Temple University, Philadelphia, PA; [d]University of Eastern Finland, Joensuu, Finland; [e]Wildlife Diversity Division, Pennsylvania Game Commission, Harrisburg, PA; [f]Institute of Integrative Biology, University of Liverpool, Liverpool L69 3BX, UK; [g]Wisconsin Department of Natural Resources, Madison, WI ; [h]Biological Sciences, Ohio University, Athens, OH

Objectives: We have employed a dual RNA-Seq approach to study gene expression of both host and pathogen during the fungal infection that causes white-nose syndrome (WNS) in bats. **Results**: We have found that when *Pseudogymnoascus destructans* is causing WNS, the most significant differentially expressed genes in the pathogen were involved in heat shock responses, cell wall remodeling, and micronutrient acquisition. These results demonstrate that this fungal pathogen responds to host-pathogen interactions by regulating gene expression in ways that may contribute to evasion of host responses. We have also found that host responses vary between susceptible and resistant species of bats in ways that may indicate that host responses contribute more to pathogenesis than to protection. This may be because, during hibernation, host immune responses are too costly and lead to premature depletion of energy reserves. We have also determined which host transcriptomic responses to fungal infection can occur during torpor and which require arousal to euthermy. We found relatively few host transcripts that showed significant changes in expression levels due to fungal infection in torpid bats compared to euthermic bats. **Conclusions**: These results support the view that torpor is a period of relative dormancy and suggest that periodic euthermic arousals exist to provide an opportunity for host responses to pathogens.

Resistance or Tolerance – How do European bats cope with *Pseudogymnoascus destructans*?
FRITZE M[1,2], VOIGT CC[2], CZIRJAK GA[2], PUECHMAILLE SJ[1,3].

[1] Zoology Institute,University of Greifswald,Soldmann-Str. 14, D - 17487 Greifswald, Germany; [2] Leibniz institute for Zoo and Wildlife Research, Alfred-Kowalke-Str. 17, 10315 Berlin, Germany and [3] School of Biology and Environmental Sciences, University College Dublin, Belfield, D4 Dublin Ireland

Objectives: *Pseudogymnoascus destructans* (*Pd*), the causing agent of the White-nose disease, colonizes bats during hibernation. The cold-loving fungus affects the snout and all the hairless skin membranes of torpid bats where it causes lesions. The spreading epidemic in North America (so called White-nose syndrome) is characterized by mass mortalities and regional extinctions of certain bat populations. In Europe, *Pd* has been recorded since several decades as a widespread pathogen, yet it does not cause mass mortalities. Several studies confirm that *Pd* is native to Europe and appeared as a new pathogen in North America in 2006. If and how European bats adapted to the disease and why North American bats cannot cope with the fungus remains unclear. **Methods**: We analysed data from over 300 hibernacula across Europe to test for factors influencing mortality, including *Pd* infections on bats. **Results**: Our results show an overall low mortality rate of bats in Europe with no evidence of *Pd*-associated mortalities. Physiological data and blood samples from infected and non-infected European bats were analysed to investigate, if bats suffer from White-nose disease and how the immune systems reacts to fungal infections during hibernation. **Conclusions**: Our ecological, physiological and immunological results suggest resistance and tolerance of European bats towards *Pd*.

Modeling the impact of White-nose syndrome on two western bat species
C. Reed Hranac[1], Brandon J. Klüg-Baerwald[2], Yvonne A. Dzal[3], Cori Lausen[4], Jonathan C. Marshall[1,5], Sarah H. Olson[6] , David T. S. Hayman[1]

Affiliations: [1] Hopkirk Research Institute, Massey University, Private Bag, 11 222, Palmerston North 4442, New Zealand; [2] Department of Biology University of Regina, Regina, SK, Canada, 3737 Wascana Parkway, Regina, SK S4S 1T8; [3] Department of Zoology, University of British Columbia, Vancouver, BC, Canada #4200-6270 University Boulevard, Vancouver, BC V6T 1Z6, [4] Wildlife Conservation Society Canada, Kaslo, BC, Canada, P.O. Box 606, 202 B Ave, Kaslo, BC V0G 1M0; [5] Institute of Fundamental Sciences Massey University, Private Bag 11 222, Palmerston North 4442, New Zealand; [6] Wildlife Conservation Society, Wildlife Health Program 212 South Wallace Avenue, Suite 101, Bozeman, MT, 59715, USA

Objectives: The rapid westward spread of white nose-syndrome (WNS) through North America has become a critical conservation issue for endemic hibernating bat species with many Eastern populations experiencing steep declines over the last ~10 years. The continued spread of the psychrophilic fungus *Pseudogymnoascus destructans* into Western states over the last two years has the potential to impact many hibernating species. Disease outcome varies widely between species, with infection of some species (namely European and Asian species) being largely benign. The identification of species that may be threatened is paramount to development of effective conservation strategies. **Methods:** Using field obtained morphometric data in conjunction with experimentally obtained estimations of key metabolic parameters we applied a modified hibernation model that includes fungal growth dynamics for two currently unaffected North American bat species: *Myotis californicus* and *Myotis yumanensis*. **Results:** Infection of *P. destructans* would likely reduce the maximal time spent in hibernation for both Western *Myotis* species. Reductions of maximal time spent in torpor were predicted to be the most drastic in microclimates with relative humidity approaching saturation and temperatures between ~5 °C and 10 °C. Despite the increased rate of overwinter energy consumption, fat reserves were still predicted to be sufficient to overwinter throughout the majority of their distribution. **Conclusions:** *M. californicus* and *M. yumanensis* are predicted not to experience distribution wide population declines like those witnessed for *M. lucifugus* and *M. septentrionalis* in eastern North America. Continuing field studies will provide data on important model parameter estimations, more species, realized hibernacula microclimate selection, and providing data to empirically validate model predictions.

Variable behaviors influence species susceptibility to disease – surviving white-nose syndrome.
Paul M. Cryan, Research Biologist,
U.S. Geological Survey (USGS), USGS Fort Collins Science Center, 2150 Centre Ave., Bldg. C, Fort Collins, Colorado 80526;

White-nose syndrome (WNS) continues to spread through populations of hibernating bats in North America, causing unprecedented mortality in several species occurring in eastern parts of the continent. Despite this devastation, other bat species that come into contact with the causative fungus, *Pseudogymnoascus destructans*, somehow survive. We still do not understand factors influencing species and continental differences in bat

susceptibility to WNS, but variability of innate behaviors among taxa and regions may help explain disease survival. This talk focuses on evidence suggesting infected bats can exploit 'survival habitats' (e.g., hibernacula with palliative microclimates) and 'survival behaviors' (e.g., palliative ways of regulating body temperature during winter). Our search for survival habitats and behaviors in WNS bats illustrates the challenges of understanding how microorganisms influence their cryptic hosts, how unknown host behaviors can obscure understanding of disease, and how new bat research methods may help overcome some of these challenges.

Emerging Insights into the Geographic Distribution, Genetic Diversity and Evolutionary Origin of Bat-borne Hantaviruses

Objective: The recent discovery of genetically distinct hantaviruses in multiple species of shrews and moles (order Eulipotyphla) prompted a further exploration of their geographic distribution, genetic diversity and evolutionary relationships by analyzing tissues and feces from bats (order Chiroptera). **Methods:** Total RNA, extracted from frozen, ethanol-fixed or RNAlater®-preserved archival tissues (lung, liver, kidney, intestine, intercostal muscle) and rectal swab/feces of 1,890 bats, representing 10 families (Emballonuridae, Molossidae, Mormoopidae, Nycteridae, Phyllostomidae, Vespertilionidae in the Yangochiroptera suborder, and Pteropodidae, Hipposideridae, Megadermatidae, Rhinopholidae in the Yinpterochiroptera suborder), collected in Asia (China, Korea, Malaysia, Mongolia, Myanmar, Philippines, Republic of Georgia, Vietnam), Africa (Côte d'Ivoire, Guinea, Liberia) and the Americas (Bolivia, Brazil, Guyana, USA) during 1981–2015, were analyzed for hantavirus RNA by nested RT-PCR. Phylogenetic analysis was performed using maximum likelihood and Bayesian methods. **Results**: Hantavirus RNAs were detected in 2 of 12 *Neoromicia nanus* from Côte d'Ivoire (Mouyassué virus, MOYV), 6 of 49 *Hipposideros pomona* and 1 of 5 *Hipposideros cineraceus* from Vietnam (Xuan Son virus, XSV), 1 of 12 *Aselliscus stoliczkanus* from Vietnam (Dakrong virus, DKGV), 2 of 13 *Taphozous melanopogon* from Myanmar (Laibin virus, LBV), and 1 of 15 *Rousettus amplexicaudatus* from the Philippines (Quezon virus, QZN). Multiple attempts to acquire whole genomes of the newfound hantaviruses were unsuccessful, except for DKGV and QZNV. Phylogenetic analyses indicated incongruent topologies for each genomic segment, presumably because of the limited sequences available for most of the hantaviruses harbored by bats, shrews and moles. However, in both the S- and L-segment trees, QZNV appeared to share a common ancestry with XSV and LBV. Based on the host cytochrome *b* sequences, the phylogenetic positions of bats in the Yinpterochiroptera and Yangochiroptera suborders were consistent with the phylogenetic relationships among the bat-borne hantaviruses. **Conclusions:** Other research teams have reported Magboi virus in *Nycteris hispida* from Sierra Leone, Makokou virus in *Hipposideros ruber* from Gabon, Huangpi virus in *Pipistrellus abramus* from China, Longquan virus in *Rhinolophus affinis, Rhinolophus monoceros* and *Rhinolophus sinica* from China, Laibin virus in *Taphozous melanopogon* from China, and Brno virus in *Nyctalus noctula* from the Czech Republic, bringing to 11 the number of bat-borne hantaviruses to date. As in shrews, moles and rodents, the same hantavirus species was occasionally found in more than one bat species, and the same bat host species occasionally harbored more than one hantavirus species, suggesting that the formerly held conventional view of one hantavirus species and one host species is no longer tenable. Moreover, the basal position of the chiropteran-borne hantaviruses in phylogenetic trees and the demonstration that bat species in both suborders harbor hantaviruses suggest that primordial hantaviruses may have emerged in an early common ancestor of bats or other members of the Laurasiatheria superorder, that includes shrews and moles.

Neotropical Bats that Co-habit with Humans Function as Dead-End Hosts for Dengue Virus

Amanda Vicente-Santos[1,2], Andres Moreira-Soto[1,4], Claudio Soto-Garita[1], Luis Guillermo Chaverri[3], Andrea Chaves[2], Jan Felix Drexler[4,5], Juan Alberto Morales[6], Alejandro Alfaro-Alarcón[6], Bernal Rodríguez-Herrera [2] and Eugenia Corrales-Aguilar [1*]

[1]Virology-CIET (Research Center for Tropical Diseases), Microbiology, University of Costa Rica, San José, Costa Rica. [2]Biology, University of Costa Rica, San José, Costa Rica. [3]Exact and Natural Sciences School, National Distance Education University, San José, Costa Rica. [4]Institute of Virology, University of Bonn Medical Centre, 53127 Bonn, Germany.[5]German Centre for Infection Research, Bonn-Cologne, Germany.[6] Department of Pathology, School of Veterinary Medicine, National University, Costa Rica

Objective: Several studies have shown Dengue Virus (DENV) nucleic acids and/or antibodies present in Neotropical wildlife including bats, suggesting that some bat species may be susceptible to DENV infection. Here we aim to elucidate the role of house-roosting bats in the DENV transmission cycle. **Methods**: Bats were sampled in households located in high and low dengue incidence regions during rainy and dry seasons in Costa Rica. We captured 318 bats from 12 different species in 29 households. Necropsies were performed in 205 bats to analyze virus presence in heart, lung, spleen, liver, intestine, kidney, and brain tissue. **Results**: Histopathology studies from all organs showed no significant findings of disease or infection. Sera were analyzed by $PRNT_{90}$ for a seroprevalence of 21.2% (51/241), and by PCR for 8.8% (28/318) positive bats for DENV RNA. From these 28 bats, 11 intestine samples were analyzed by RT-PCR. Two intestines were DENV RNA positive for the same dengue serotype detected in blood. Viral isolation from all positive organs or blood was unsuccessful. Additionally, viral load analyses in positive blood samples by qRT-PCR showed virus concentrations under the minimal dose required for mosquito infection. Simultaneously, 651 mosquitoes were collected using EVS-CO_2 traps and analyzed for DENV and feeding preferences (bat cytochrome b). Only three mosquitoes were found DENV positive and none was positive for bat cytochrome b. Our results suggest an accidental presence of DENV in bats probably caused from oral ingestion of infected mosquitoes. Phylogenetic analyses suggest also a spillover event from humans to bats. **Conclusion**: Therefore, we conclude that bats in these urban environments do not sustain DENV amplification, they do not have a role as reservoirs, but function as epidemiological dead end hosts for this virus.

Novel Gammaherpesvirus in Bats: discerning the secrets of these oncogenic viruses

Sonu Subudhi[1], Noreen Rapin[1], Janet Hill[1] and Vikram Misra[1]

[1]Department of Veterinary Microbiology, University of Saskatchewan, Saskatoon, Canada

Objectives: *Gammaherpesvirinae* is a subfamily of herpesviruses which often cause lymphoproliferative diseases and have been linked to two human lymphoid cancers – Burkitt's lymphoma and Kaposi's sarcoma. Anecdotal evidence suggests that bats have lower rates of cancer than other mammalian species. This phenomenon may be because bats have evolved efficient mechanisms for detecting and repairing damaged DNA as a by-product of flight. How such a mechanism affects the interaction of Gammaherpesviruses (which cause cancer) with their bat, hosts is largely unknown. **Methods and Results:** We have isolated a novel Gammaherpesvirus (*Eptesicus fuscus* herpesvirus – EfHV) from a North-American Big Brown bat (*Eptesicus fuscus*). We have used a big brown bat cell line to study the growth kinetics of the virus. We have also performed electron microscopy and PCR to confirm that the virus belongs to the herpesvirus family. To determine the sequence of the herpesvirus, we have performed next generation sequencing (NGS) using Illumina mi-seq. Using the sequence obtained, we have performed phylogenetic analysis from which we found that although the EfHV belongs to the sub-family of Gammaherpesvirus, it forms a distinct branch within the sub-family. In addition to that we have identified the different proteins present in the virion by performing mass spectroscopy and have found that the virion components are similar to other herpesviruses. We have also infected cells of different species with the EfHV to understand the spectrum of different species that this virus is capable of infecting and we have found that it is able to infect human, monkey, porcine and feline cell lines apart from the bat cell line. **Conclusions:** The phylogenetic analysis shows that EfHV is a distant relative of all other gammaherpesviruses known so far. It might have evolved together with the big brown bat. Further studies looking at the interaction of EfHV and big brown bat might help us understand more about the persistent infection in bats and their unique was of resisting cancer.

Experimental Infection of Jamaican Fruit Bats (*Artibeus jamaicensis)* with Zika Virus

Ashley Malmlov[1], Kaitlyn Miedema[1], Tawfik Aboellail[2], Corey Rosenberg[1], Miles Eckley[1], Nunya Chotiwan[1], Rebekah C. Gullberg[1], Rushika Perera[1] and Tony Schountz[1]

[1]Arthropod-Borne and Infectious Diseases Laboratory, Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, Colorado, USA and [2]Veterinary Diagnostic Laboratories, Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, Colorado, USA

Objectives: Zika virus (ZIKV) emerged in the New World with the 2014 outbreak in Brazil. It has spread to much of South America, Central America, Mexico and the Caribbean, with hundreds of thousands of cases. While disease presentation may be subclinical to mild and include symptoms of maculopapular rash, conjunctivitis, and arthralgia, infection of pregnant women can lead to fetal microcephaly. Additionally ZIKV infection can induce Guillain-Barre syndrome. In the 1950s and 1960s bat species were investigated as possible reservoirs for ZIKV. In total, five different species of bats were found to be susceptible to the virus. Bats seroconverted, had viremia,

and, in one experimental infection study bats developed fatal neurological disease. This warranted further investigation of ZIKV in bats to determine their use as an animal-model, and to better understand the potential role of bats in viral ecology. **Methods:** Nine Jamaican fruit bats (*Artibeus jamaicensis*) were subcutaneously inoculated with $7.5x10^5$ pfu of ZIKV strain PRVABC59 and monitored over the course of 28 days, during which there were no conspicuous signs of disease. Bats were euthanized at 2, 5, 10 and 28 days post-inoculation to assess the course of infection and antibody responses. **Results:** Bats seroconverted by day 28 by ELISA with ZIKV-infected, fixed Vero E6 cells. Low levels of viral RNA were detected in one brain and one urine sample. IHC detected ZIKV antigen in lung and testes of one bat, and brains and salivary gland of two others. Pathology was consistently observed in the lungs, heart, testes and brain. Pneumonia was observed in four bats, cardiomyocyte necrosis in three bats, degeneration and lymphocyte infiltration in the testes of two bats, and neuronal degeneration in the hypothalamus and cerebellum in three bats. **Conclusions:** These results provide evidence that Jamaican fruit bats are susceptible to ZIKV and may serve as an animal model to study neurological components and sexual transmission of the virus. Low viral load in urine and tissues suggests the role of bats in viral ecology may be minimal.

Long-term monitoring of *Bartonella* bacteria in a captive colony of fruit bats and experimental evidence of bat flies as vectors of bartonella

Clifton McKee[1,2], Colleen Webb[1], Michael Kosoy[2], Ying Bai[2], Lynn Osikowicz[2], Richard Suu-Ire[3], Yaa Ntiamoa-Baidu[4], Andrew Cunningham[5], James Wood[6], David Hayman[7]

[1]Department of Biology, Colorado State University; [2]Division of Vector-Borne Diseases, Centers for Disease Control and Prevention; [3]Wildlife Division, Forestry Commission of Ghana; [4]Department of Animal Biology and Conservation Science, University of Ghana; [5]Institute of Zoology, Zoological Society of London; [6]Department of Veterinary Medicine, University of Cambridge; [7]Institute of Veterinary, Animal and Biomedical Sciences, Massey University

Objectives: Few experimental studies have monitored long-term infection dynamics in bat populations. This is especially true for vector-borne bacteria, where there can be significant challenges in maintaining both host and vector populations in controlled settings. In order to understand the importance of vector populations in the long-term maintenance of infection prevalence and bacterial diversity, we advocate for the use of semi-natural, long-term experiments capable of detecting changes in infection dynamics linked to the force of infection by vectors. **Methods:** Using blood samples taken from a captive colony of ~100 fruit bats (*Eidolon helvum*) in Accra, Ghana from July 2009 - March 2012, we monitored the dynamics of *Bartonella* spp. infection in the bat population using molecular techniques. Over this period, the bat fly population (*Cyclopodia greefi*) infesting the captive bats declined, but was then supplemented with additional flies from wild *E. helvum* in January 2012. We hypothesized that prevalence and species diversity of *Bartonella* infections in the colony will vary with changes in the bat fly population. **Results:** *Bartonella* prevalence and diversity peaked in March 2010 with 77% of bats infected and 8 *Bartonella* spp. present, then began to decline until July 2011 with only 15% of bats infected and 4 *Bartonella* spp. present. After the reintroduction of flies in January 2012, prevalence increased to 43% in March 2012 with 6 species present. Bats that received flies were equally likely to become positive after January 2012 as bats that did not receive flies, which may be attributable to dispersal of flies among bats after reintroduction. Additionally, changes in relative *Bartonella* spp. abundances showed that the species lost over time were uncommon in bats, but some of these uncommon species became more abundant after the reintroduction of flies. **Conclusions:** This experiment indicates that *C. greefi* bat flies are likely vectors of bartonella in *E. helvum* and play an important role in the maintenance of bacterial diversity in bats. Ongoing occupancy modeling work will explore the influence of within-host processes (including bacterial interactions and host resistance to infection) and alternative transmission routes on the long-term infection dynamics in individual bats.

1. Predicting the epizootiology of temperate bat disease: Is it all about the bats?James N. Aegerter[1], Ashley C. Banyard[2], Anthony R. Fooks[2], Graham C. Smith[1]

[1]Animal and Plant Health Agency (National Wildlife Management Centre), Sand Hutton, York, UK. [2] Animal and Plant Health Agency (Weybridge), New Haw, Addlestone, UK

Predicting the dynamics of disease in wild bats, their epizootiology, and the risks these pose to people, the economy or other biodiversity is complicated. Bats may be the evolved hosts for disease, effective maintenance hosts, or accidental spill-over hosts (we cannot always distinguish which), whilst their unique life-style permits the exceptional natural movement of disease, as well as an exceptional potential to vector disease into homes, farms or other sensitive sites. These diseases may pose social or economic concerns (i.e. to public or livestock health), or produce conservation concerns. Further, diseases may well also be endemic, exotic or newly emerging, and importantly their dynamics today occur in the contexts of rapid land-use change and climate change. With decision-makers relying on the quality of epizootiological predictions, and substantial uncertainty about the pathogen, its pathology in wild bats, a changing environment, and the abstraction of these into mathematical form, it is surprising that little effort has been made to construct and validate mechanistically realistic models of bat populations to act as the solid foundation for higher-level disease modelling. Here we aim to produce a generic tool to provide some evidence based predictions of bat disease epizootiology, founded on a coherent representation of bat ecology and behaviour deployed through an IBM (Individual Bat Model). Importantly, this is founded on an independently validated understanding of their ecology and population dynamics, both of which need to emerge as model behaviour before disease is added. We recognise at least two divergent life-history strategies and lifestyles; ‘slow’ bats, typified by cave hibernators, include a seasonal hierarchical spatial and population structure; ‘fast’ bats show larger but less structured communities. Both accommodate the emerging understanding of bats as social animals as well as assuming that spatial heterogeneity drives some form of meta-population process. Early work has illustrated the surprising variation/instability in demographic structure driven by environmental variation close to range edges (many British bats are at their cold edge in the UK), as well as highlighting basic gaps in knowledge which are pivotal in robust predictions of disease dynamics (males in summer – Where? When? And how much?).

2. **Comparative loss of function screens highlight common cellular pathways required by mumps virus for replication in bats and humans**

Objectives: Bats have been implicated as an important source of new and emerging paramyxoviruses. The identification of bat-borne paramyxoviruses closely related to mammalian paramyxoviruses suggests a possible risk of zoonotic transmission of these paramyxoviruses. Mumps virus (MuV) a contagious virus of the genus *Rubulavirus*, was thought to be an exclusive human pathogen with no animal reservoir. Recently, the complete genomic sequence of a mumps-like rubulavirus was obtained from an African bat. In order to ascertain if bat and human cells are capable of supporting the replication of MuV, and to identify cellular proteins involved in the viral life cycle, we performed comparative genome scale siRNA screens using a human and novel bat siRNA library. **Methods**: Comparative genome scale siRNA screens with MuV were performed. The human MuV siRNA screen (Qiagen) was previously performed in our lab using A549 cells, a human lung adenocarcinoma cell line. A custom bat siRNA library was designed to target 18,328 genes of the *Pteropus alecto* genome. The bat siRNA screen was performed in PaKi cells, a *Pteropus alecto* kidney cell line. **Results**: The coatomer complex I, a known dependency factor was identified as required for MuV replication in both human and bat cells. Eukaryotic initiation factor 3 (eIF3) is a multiprotein complex that functions during the initiation phase of eukaryotic translation was also identified as a host factor. Interestingly, ABCE1, identified as a pan-paramyxovirus host factor, was not required for MuV replication in bat cells. **Conclusions**: This study is the first to utilize a bat genome scale siRNA screen and provides a novel overview of cellular proteins and pathways that impact this important pathogen.

3. **Implementation of a RT-PCR Assay to Detect Henipaviruses in Trinidad Bats**
Victoria Avanzato[1], Neeltje van Doremalen[1], Christine Carrington[2], Janine Seetahal[2], Tony Schountz[3], Vincent Munster[1]

Objectives: Since the emergence of Hendra in Australia, and Nipah in Malaysia and Bangladesh, evidence of henipaviruses in bats has been reported in Thailand, Cambodia, India, Papau New Guinea, China, and Madagascar. Cedar virus, a novel henipavirus, has been isolated from bats in Australia. There has been evidence of seropositivity among humans and *Eidolon helvum* (Straw-coloured fruit bat) bats in Cameroon, as well the publishing of the genome sequence of a henipa-like virus from a bat sample in Ghana. More recently, sequences related to henipaviruses were identified in New World bats, and Brazilian bats were found to have antibodies against henipa-like viruses, though no viral isolate has yet been obtained. This suggests that henipaviruses are likely to exist in other regions, including the Western hemisphere, presenting a need to investigate host populations. The goal of this study is to design a PCR assay to screen bat samples from Trinidad to detect novel henipa or henipa-like viruses.
Methods: Using published primer sets from Tong, et al, and van Boheemen, et al, PCR assays were developed to screen various tissue samples collected from bats in Trinidad. Both primer sets will be evaluated for their ability to detect henipaviruses using viral RNA standards for Hendra, Nipah Bangladesh, and Nipah Malaysia. The 132 samples are from 30 bats, including the species *Saccopteryx bilineata* (greater sac-winged bat), *Carollia perspicillata* (Seba's short-tailed bat), and *Artibeus planirostris* (Flat-faced fruit-eating bat) (sensu Larsen, 2007). Tissues harvested include brain, kidney, liver, spleen, lung, and fetal tissue.
Results: The PCR assay is able to detect viral RNA standards of Hendra, Nipah Bangladesh, and Nipah Malaysia. The assay will be further optimized to screen tissue samples. Samples that screen positive by this assay will be sequencinged.
Conclusions: To our knowledge, no henipaviruses have yet been detected or isolated from New world bats, though studies suggest their presence. Thus, screening for novel henipaviruses in Trinidad bats will help elucidate the full geographic range of these viruses, allowing a better understanding of risks of emergence and outbreaks in humans.

4. **Genomic characterization and pathogenic potential of a novel evolutionarily-divergent alphacoronavirus isolated from *M. lucifigus* bats in Alaska.**

4- Dept. of Veterinary Medicine, University of Alaska Fairbanks

Objectives: Coronaviruses (CoV) are zoonotic pathogens with the potential to cross species barriers from bats into other mammals, including marine mammals, swine and humans. Novel bat-origin coronaviruses have been responsible respiratory disease in humans, notably betacoronaviruses (OC43, HKU-1, SARS and MERS) and alphacoronaviruses (229E and NL63). Thus, it is important to identify the reservoirs of CoV in bats and their potential for transmission, and pathogenicity, in other mammalian species. We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus,* the little brown bat.

Methods: Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. Total RNA extracts were screened by RT-PCR with coronavirus primers matching CoV ORF1a, and amplicon sequencing. Complete genomes of novel viruses were sequenced by next-generation sequencing (NGS) RNA-seq.

Results: Sanger sequencing of amplicons confirmed the presence of an alphacoronavirus phylogentically related to persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. Primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. Aligning to a reference *M. lucifigus* virus from Colorado, bat alphacoronavirus CDPHE15/USA/2006, we assembled a full-length genome (28,515nt) identifying the novel alphacoronavirus/bat/Alaska/s7/2014. A high

degree of thermodynamically stable stem-loop RNA structures are predicted by Mfold within 700nt of 5' and 3' termini of genome**.** While nucleotide conservation to the Colorado virus was 96%, notable amino acid differences were identified in coronavirus proteins. The major CoV surface spike (S) protein exhibited 26 amino acid changes, including 14 in the globular head containing the putative receptor-binding domain, suggesting divergence based on immune evasion or receptor-specificity. Another 6 amino acids were altered in the fusion hinge. Protease cleavage sites were not conserved. Nucleoprotein (N) and ORF3 also exhibited amino acid differences.

Conclusions: Understanding the evolution and pathogenicity of this novel evolutionarily-divergent alphacoronavirus provides insight into the role of bats in virus transmission, and ecological assessment of bat-borne virus reservoirs in North American ecosystems.

5. Preliminary Evidence of Secondary Acquisition of Tymoviridae and Partitiviridae in Little Brown Bats (*Myotis lucifugus*) in Southcentral Alaska.

1 Dept. of Biological Sciences, University of Alaska Anchorage
2 Battelle Memorial Institute
3 National Center for Genome Resources, santa Fe NM
4 Dept. of Veterinary Medicine, University of Alaska Fairbanks

We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus,* the little brown bat. Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. Total RNA extracts were screened by RT-PCR and CoV ORF1a, and primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. Sanger sequencing of amplicons confirmed the presence of an alphacoronavirus phylogenetically related to persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. In two distinct bat samples, preliminary results indicate the likely presence of tymovirus (eg. Dulcama mottle virus) probably acquired through ingestion of insects feeding on infected plants. In addition, initial results indicate presence of β-partitivirus closely aligned to *Rosellina*-type associated with spruce/alder and other partitivirus-like sequences. Secondary acquisition of virus obtained by feeding or incidental infection by fungi (eg. γ-partitivirus associated with *P. destructans*) has been previously described for bats collected from similar ecological settings (eg. Thapa *et al.* 2016). We continue to further refine these initial for better resolution of the virome of Alaska bats.

6. Molecular Screening of Zika and Dengue Viruses in Bats (*Artibeus jamaicensis, Glossophaga longirostris* and *Molossus molossus*) from Grenada, West Indies.

Marcy Kanuka[1], Ashley Malmlov[2], Christine Cornish[1], Kathleen Parker[1], Cassandra Tang Wing[1], Diana Stone[1], Tony Schountz[2] and Sonia Cheetham[1]

[1]Department of Pathobiology, School of Veterinary Medicine, St. George's University, Grenada, West Indies; [2]Department of Microbiology, Immunology, and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Colorado, USA

Background: In recent years Zika virus (ZikV) has changed from an uncommon and poorly documented infection to a global public health concern. Dengue virus (DenV) has long-standing human health concerns worldwide, including Grenada, and has been detected in bats from other tropical countries. **Objective**: To determine if Grenada bats are infected with ZikV and DenV and thus possible reservoir hosts for these viruses. **Methods**: Forty-nine bats from 3 different genera and feeding behaviours (frugivorous, nectivorous and insectivorous) were trapped and humanly euthanized. ZikV RT-PCR was performed on serum, testes, spleen and brain samples, and a DenV RT-PCR multiplex was performed on serum. Amplicons of the expected sizes were sequenced for confirmation. **Results**: Physical exams prior to euthanasia and sample collection indicated all bats were clinically healthy. All 3 bat species collected tested positive for both viruses. Sera from 27 bats out of 41 tested were positive for ZikV (65.9%) and sera from 12 bats out of 19 tested were positive for DenV (63.2%). All DenV positive bats were infected with serotype 2, with one of these bats testing positive for both DenV serotype 2 and 4. Brains from 22 bats out of 48 tested were positive for ZikV (45.9%). Testes from 2 bats out of 12 tested were ZikV positive (16.7%) and a spleen from one bat out of 22 tested was ZikV positive (4.5%). **Conclusions**: The results demonstrate that frugivorous, nectivorous and insectivorous bats in Grenada are infected with both ZikV and DenV. Of interest is that despite many bats testing positive for ZikV in the brain, all bats appeared clinically healthy with no signs of neurologic dysfunction. Histopathology and immunohistochemistry are pending to

determine if infection is associated with lesions. Virus quantification is currently underway to determine if the level of viremia for either ZikV or DenV is high enough to consider the different bat species as potential reservoir hosts.

7. Serologic evaluation of Alphavirus and Flavivirus exposure in bats in Grenada

Diana Stone[1], Christine Cornish[1], Amy C. Lyons[2], Yan-Jang S. Huang[2], Dana L. Vanlandingham[2], Stephen Higgs[2], Bradley Blitvich[3], Abiodun A. Adesiyun[4], Sharlene Santana[5], Leith Leiser-Miller[5], Sonia Cheetham[1].

[4]Department of Basic Veterinary Sciences, School of Veterinary Medicine, University of the West Indies, Trinidad and Tobago.
[5]Department of Biology and Burke Museum of Natural History and Culture, University of Washington, Seattle, WA, USA.

Objective: Determine exposure to Alphaviruses and Flaviviruses in bats in Grenada. **Methods:** Fifty bats were trapped in August, 2015 in Grenada. Sera from all bats were tested for antibodies to flaviviruses: West Nile virus, Japanese Encephalitis virus, St. Louis Encephalitis virus, Bussuquara virus and dengue virus serotypes 1-4 (DENV-1,2,3,4) using the plaque reduction neutralization test (PRNT). Forty three of the 50 samples were tested for antibody to alphaviruses: Western Equine Encephalitis virus, Venezuelan Equine Encephalitis virus and Eastern Equine Encephalitis virus using epitope-blocking ELISA and 42 samples were tested for antibody to the alphavirus Chikungunya (CHIKV) using PRNT. **Results and Conclusions:** Two species of fruit bats were sampled, *Artibeus jamaicensis*, (48), and *A. lituratus*, (2). Fifteen of the 42 tested positive for neutralizing antibodies to CHIKV at $PRNT_{50}$ with titers 1:10 to 1:640. All 43 bats tested negative for epitope blocking antibody to the other alphaviruses except one positive for Venezuelan Equine Encephalitis virus. All 50 bats tested negative for neutralizing antibody to flaviviruses except one which had a Bussuquara virus $PRNT_{80}$ titer of 20. **Discussion:** Historically, DENV has been endemic in Grenada. CHIKV was introduced to the island in 2014. Bats for this study were trapped a year after the peak human CHIKV epidemic. Of interest is that in a separate study molecular detection confirmed the presence of both DENV and CHIKV RNA in bats serologically tested in this study. Of the 15 CHIKV seropositive bats, one was positive for CHIKV RNA. Of the 50 DENV seronegative bats, 6 showed detection of flavivirus RNA with a band compatible with DEN3. Thus, the negative DENV serology is unanticipated, but may reflect lack of neutralizing antibody responses developed for DENV. Future studies will characterize the humoral immune response to DENV in naturally exposed Grenada bats and determine whether non-neutralizing antibody responses are present. The type of immune response to DENV in bats may promote persistent infection and high-titer viremia and thus contribute to viral maintenance. Our results and those of the molecular study confirm that Grenada fruit bats are exposed to CHIKV and DENV, but their role in the epidemiology of these viruses is currently unknown.

8. **Isolation and molecular characterization of Bukakata orbivirus, a novel virus from a Ugandan bat, and associated pathology in experimentally infected Jamaican fruit bats (*Artibeus jamaicensis*)**

Fagre AC, Kityo R, Lee J, Mossel E, Crabtree, M, Nalikka B, Nakayiki T, Kerbis J, Gilbert, A, Bergren, N, Nyakarahuka L, Lutwama J, Stenglein M, Byas A, Malmlov A, Bergren N, Rice L, Miller B, Schountz T & Kading, RC.

Objectives: In 2013, a novel orbivirus (*Reoviridae: Orbivirus*) was isolated from an Egyptian fruit bat (*Rousettus aegyptiacus*) in Uganda. Preliminarily named "Bukatata orbivirus" after the region where the infected bat was captured, this virus is the fourth identified orbivirus of bats. The genomes of all four bat orbiviruses (Bukakata, Ife, Fomede, and Japanaut viruses) were sequenced to assess their phylogenetic placement within the genus *Orbivirus*, and develop hypotheses regarding virus-vector associations. **Methods:** Whole genomes of all four viruses were sequenced using an Illumina platform and assembled *de novo*. To begin studying the effect of infection with Bukakata orbivirus on a bat host, three male Jamaican fruit bats (*Artibeus jamaicensis*) were inoculated intraperitoneally with 5.3 $\log_{10}$ pfu Bukakata orbivirus and monitored daily for signs of clinical disease. **Results:** Phylogenetic analysis placed Fomede and Bukakata orbiviruses in the tick-borne clade, and Japanaut and Ife in the mosquito/*Culicoides* clade. On day 12, all three bats were diffusely hyperemic and tachypneic and, thus, were humanely euthanized. Histopathologic lesions of perivascular inflammation, hemorrhage and edema were present in varying degree of severity in the liver, lung and kidney of all three bats. Additional lesions included meningeal hemorrhage in two of the bats and evidence suggestive of early hepatic vasculitis in the other. Eosinophilic and suppurative gastroenteritis affected all bats with one containing intraluminal bacilli, suggesting secondary bacterial infection. **Conclusions:** Immunohistochemistry and qPCR will be performed to assess

relative abundance of virus in various organ systems to optimize future analyses. Future experimental infections will be performed to monitor temperature, physiological and immune parameters, virus shedding and viremia throughout the course of infection. These preliminary data are critical in the assessment of the potential role of bats as reservoirs for arboviruses.

9. **Using GIS to Guide Ebola Virus Disease Ecology Field Investigations**

Robert J. Fischer[1], Seth D. Judson[1,2], Sarah H. Olson[3], Vincent J. Munster[1]
[1]Virus Ecology Unit, Laboratory of Virology, Rocky Mountain Laboratories, NIAID, NIH Hamilton, MT; [2]David Geffen School of Medicine at UCLA, Los Angeles, California; [3]Wildlife Conservation Society, Bronx, New York

Objectives: In the health field GIS is being used to track epidemics in real time and to create predictive models of outbreak potential. We have investigated the feasibility of using a maximum entropy model (Maxent) to assist in determining the target species and optimum locations and times to direct field sampling efforts. **Methods:** We developed an ecological niche model of Ebola virus (EBOV) using the location of Ebola virus disease (EVD) outbreak index cases as presence points we developed an ecological niche model to predict geographic locations that had environmental conditions similar to those of known outbreaks. To determine which environmental parameters were important in constructing the model, a correlation matrix was constructed using ArcGIS and highly correlative parameters were eliminated and the model reconstructed. Additionally, home ranges of African mammals were overlaid on a map and compared to the model to determine which species inhabit the geographical regions predicted to be suitable for a spillover event. **Results:** The model was used to highlight environmental factors common to the location of the EVD index cases from 19 environmental parameters and altitude that were used to construct the model. A list of 66 mammals including 26 bat species with home ranges that overlap the modeled range of EBOV was produced. **Conclusions:** While there is no conclusive evidence that bats serve as the reservoir for Ebola virus (EBOV) i.e. there is no wild EBOV bat isolate, there is evidence that they may play a role in maintaining the virus in nature. Combining what is known about the natural histories of bat species and animal species known to be susceptible to EVD such as great apes, duikers and forest hogs coupled with environmental factors predicted to be important, we can further prediction when and where spillover events may occur and tailor our sampling efforts to target these conditions. Additionally, as there is a dearth of knowledge on the natural history of deep forest fruit bats we are planning to monitor the short term daily movements of *Hypsignathus monstrosus* with the aim of being able to predict where the movements of the bats and susceptible species may commonly intersect.

10. **Bat - infection interactions: Signals of evolution, ecology, immunity and deforestation**

Hannah Frank[1], David Enard[1], Chase Mendenhall[1,2,3], Ji-Yeun Lee[4], Ellie Armstrong[1], Stefan Prost[1], Seth Judson[5], Jamieson O'Marr[1], Gretchen Daily[1,3,6], Dmitri Petrov[1], Scott Boyd[4] and Elizabeth Hadly[1,6,7]

[1] Department of Biology, Stanford University; [2] The Nature Conservancy; [3] Center for Conservation Biology, Department of Biology, Stanford University; [4] Department of Pathology, Stanford University; [5] David Geffen School of Medicine, University of California, Los Angeles; [6] Stanford Woods Institute for the Environment, Stanford University; [7] Center for Innovation in Global Health, Stanford University

Objectives: Bats are ecologically diverse and these ecological differences may lead to differences in infection prevalence and identity. We sought to discover the evolutionary and ecological signatures of differences in bat behavior and environment on bat-infection patterns, as well as to understand how these patterns are impacted by human activity. Regions where a high diversity of hosts occur with prevalent deforestation, human habitation and livestock rearing are of great concern for potential spillover. Accordingly, we aimed to characterize infections of potential spillover importance in an altered landscape. **Methods**: Using a combination of genomics, targeted sequence capture and tests of positive selection, we screened 60 species of bats distributed globally for evidence of selection in response to viruses. Additionally, we screened the speciose and ecologically diverse bat fauna of an agricultural landscape in Costa Rica for eight viral groups (Herpesviridae, Astroviridae, Adenoviridae, Paramyxoviridae, Coronaviridae, *Lyssavirus*, Filoviridae, Influenza A), *Bartonella* bacteria and ectoparasites to detect pathogen sharing, immunological and behavioral patterns of infection and the impact of humans on these relationships. **Results**: Evolutionarily, viral sharing has been important for shaping bat immune evolution. However, ecologically most infections are host specific and regulated by host immunity with species that are more frequently exposed less likely to yield detectable pathogen nucleic acids. In deforested areas, these patterns shift in a sex-specific manner, disproportionately impacting females with potential for population stability. **Conclusions**: This study yields evolutionary insights into the unique relationship between bats and viruses, identifying the environmental factors that are driving adaptation. Additionally, it represents one of the broadest infection screening studies in the Neotropics, which has the highest density of bat diversity but is less frequently screened than the Old World. Our data suggest that there are few pathogens of spillover concern circulating in this landscape, but that humans may be having a detrimental impact on bat health.

Daytime behavior of *Pteropus vampyrus* and *Acerodon jubatus* in the natural habitats: a cue of viral transmission

11. Yupadee Hengjan[1], Didik Pramono[2], Hitoshi Takemae[1], Ryosuke Kobayashi[1], Karla Cristine Doysabas[1], Keisuke Iida[1], Takeshi Ando[5], Supratikno[2], Chaerul Basri[2], Yuli Sulistya Fitriana[4], Eko M.Z. Arifin[6], Yasushige Ohmori[1], Ken Maeda[3], Srihadi Agungpriyono[2] and Eiichi Hondo[1]

[1]Graduate School of Bioagricultural Sciences, Nagoya University; [2]Faculty of Veterinary Medicine, Bogor Agricultural University; [3]Joint Faculty of Veterinary Medicine, Yamaguchi University; [4]Research Center for Biology, Indonesian Institute of Science, Indonesia; [5]Japan International Cooperation Agency; [6]Livestock, Fisheries and Marine Services, Indonesia

Objectives: The large flying fox (*Pteropus vampyrus*) are well-recognized host of Nipah virus. Base on serologic studies, the golden-crowned flying fox (*Acerodon jubatus*) are infected with Ebola Reston virus. To estimate the risk of disease emergence, it is important to understand the behavior of flying foxes. This study aimed to clarify diurnal behavior of *P. vampyrus* in Leuweung Sancang conservation area, Indonesia (7º 43′ 45.12″ S, 107º 54′ 10.08″ E), and *A. jubatus* in the Subic Bay Freeport, the Philippines (14º 46′ 31.54″ N, 120º 19′ 14.90″ E). **Methods:** Quantitative behavioral data were collected using instantaneous scan sampling and all occurrence focal sampling methods. **Results:** Unexpectedly, many flying foxes were awake during daytime (*P. vampyrus*: 46.9 ± 10.6%, *A. jubatus*: 23.7 ± 3.1% of scanned bats), and showed various activities. The commonly observed behavior were wing flapping and self-grooming behaviors. Males engaged in sexual activity more than females (*P. vampyrus*: 6.5 ± 1.6 % in males and 0.2 ± 0.1 in females, *A. jubatus*: 1.6 ± 0.5 % in males, 0% in females), sometimes accompanying with aggression behaviors between males and females. There was no significant difference in negative social behaviors (fighting and wing spreading) between males and females of *P. vampyrus*, whereas, the difference was found in *A. jubatus* (2.6 ± 0.7 % in males, 0.1 ± 0.04 % in females). The positive social behaviors (maternal care, mutual grooming and playing) were rarely found in *P. vampyrus*, but never in *A. jubatus*. Physical communications, not only among flying foxes, but also direct and/or indirect contacts between *P. vampyrus* and non-human primate (*Trachypithecus auratus*) were observed (3.3 ± 0.5 times per day). Specifically, periodic disturbance by tourists and unidentified aerial predators like raptors was observed at the roosting site of *A. jubatus*. *A. jubatus* shared the same roosting site with *P. vampyrus*, this enables the contacts between the two species of flying foxes, an average 25.4 ± 6.3 times per day. **Conclusions:** These observations would provide a cue to know how viral transmissions among flying foxes, other wildlife and humans in South-East Asia.

12. The study of whole spike gene of bat coronavirus from Thailand using Next Generation Sequencing

Yutthana Joyjinda[1], Supaporn Wacharapluesadee[1], Prateep Duengkae[2] , Apaporn Rodpan[1], Teerada ponpinit[1], Thongchai Kaewpom[1], Sangchai Yingsakmongkol[3], Kevin J Olival[4], Thiravat Hemachudha[1]

[1] The Thai Red Cross Emerging Infectious Disease Health Science Centre and World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of medicine, Chulalongkorn University, Thailand, [2] Forest Biology Department, Faculty of Forestry, Kasetsart University, Thailand, [3] Faculty of Veterinary Medicine, Department of Microbiology and Immunology, Kasetsart University, Thailand, [4]EcoHealth Alliance, New York, NY, USA

Objectives Bats have been recognized as the natural reservoirs of a vast variety of viruses, including as host to Coronaviruses – a viral family of public health importance. Bat coronaviruses have been intensively studied since the discovery of Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV) and have expanded even more after the emergence of Middle East Respiratory Syndrome Coronavirus (MERS-CoV), both of which are purposed to have originated from bats. Since spike protein is correlated with host cell receptor binding and membrane fusion, a better understanding of sequence diversity for this gene will help determine the potential for host-switching and zoonotic potential of CoVs. The aim of our study was to characterize the spike gene of bat coronaviruses from Thailand. **Methods** we PCR amplify about 4 kb of whole spike gene from seven PCR positive coronavirus of *M. magneter* and *R. shameli* bats from northern part of Thailand and sequencing using Next Generation Sequencing (NGS). Phylogenetic tree of the full alignment of whole spike gene sequences was estimated by maximum likelihood method. **Results** The average of 1,306,845 sequences of spike gene per sample was obtained from NGS. Phylogenetic tree of all seven spike sequences are grouped into the same clade in the alpha Coronavirus (α CoV) and mostly related to the Bat Coronavirus-1A (BatCoV-1A). **Conclusions** Even though seven spike genes of coronaviruses in this study showed sequence different from emerging disease beta coronavirus group B and C (β CoV B and β CoV C); nevertheless, more positive bat coronaviruses should be investigated including whole genome sequencing of bat coronaviruses that may useful for more understanding host-viral evolution and potential for host switching or spillover.

13. **Assessment of the cross-species potential of two emerging coronaviruses, SARS-CoV and MERS-CoV, by Protein-Protein Molecular Docking analyses**
Jun Li & Vincent Munster

Laboratory of Virology, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health

Objectives: Coronaviruses are a virus family with broad host range, and have spilled over from their natural reservoirs into various mammalian species, including humans. For humans, four of them cause common cold and circulate exclusively in the human population. In addition, SARS-CoV and MERS-CoV, recently emerged in the human population and are associated with severe respiratory illness. Where do these zoonotic viruses come from, and how did they cross the species barrier? These questions are generally difficult to address. The critical residues at interaction interface of host receptors (DPP4 for MERS-CoV and ACE2 for SARS-CoV) are believed to impact the binding ability of the receptors with viruses' surface-located spike. The diversity of available protein sequences limits our understanding of the receptor-mediated pathogen-host interactions for bat coronaviruses. Computational molecular docking is a bioinformatics tool, which allows us to explore the potential receptor-spike interactions in silico. The aim of this study is to analyze the diversity of SARS-CoV and MERS-CoV receptors from different mammalian hosts, to predict the host range using modeling and molecular docking. **Methods:** Up to 109 DPP4 and 94 ACE2 sequences from mammalian hosts were downloaded from genbank or acquired by sequencing, covering 60 and 51 different families respectively. The putative crystal structures were homologically modeled, and protein-protein docking was performed using Autodock Vina on NIH HPC Biowulf cluster. **Results:** Both of DPP4 and ACE2 receptors sequences from the hosts have relative high diversity. The docking results point out wide but family specific of host range of MERS-CoV and SARS-CoV. Virtual mutagenesis studies explored the impact of each critical residue of DPP4 on binding interaction for *Homo sapiens*, *Mesocricetus auratus*, *Desmodus rotundus*, *Canis lupus familiaris* and *Felis catus*. **Conclusions:** Although currently in silico analysis of spike-receptor interactions utilizing molecular docking methods still are in its early stages of development, the generated results could be utilized to perform large screens of potential virus reservoir, and intermediate hosts associated with emerging coronaviruses, and could potentially be utilized to estimate the distribution of MERS-CoV and SARS-CoV in ecosystems.

14. **Hendra virus phylogeography in eastern Australia**
Kessler MK[1], Kamath PL[2], Smith CS[3], Goldspink LK[3], Plowright RK[1]

[1] Department of Microbiology and Immunology, Montana State University, Bozeman, Montana, USA; [2] U.S. Geological Survey, Northern Rocky Mountain Science Center, Bozeman, Montana USA; [3] Queensland Center for Emerging Infectious Diseases, Biosecurity Queensland, Department of Agriculture and Fisheries, Brisbane, Queensland, Australia

Objectives: Hendra virus (HeV) is an emerging zoonotic paramyxovirus that causes sporadic fatal disease in horses and humans in mainland Australia. Australian flying foxes (*Pteropus* spp. fruit bats), the endemic host, are gregarious, semi-migratory species that occupy the tropical and subtropical forests of coastal Australia. Despite the vast range of flying foxes, current outbreaks of Hendra virus have been restricted to a narrow band in southeast Queensland and northern New South Wales. Transmission dynamics of HeV between flying foxes is poorly understood, which limits our ability to identify potential points for management and spillover prevention. We used a phylogeographic framework to explore the spatial structure of HeV over eastern Australia, and to investigate factors that contribute to maintenance and spread of HeV in flying foxes. **Methods:** A three-year surveillance field study was initiated to improve understanding of Hendra virus diversity and disease dynamics in wild flying foxes, generating partial sequences from 26 colonies across eastern Australia. We incorporated sequenced isolates from spillover events in horses, and applied discrete and continuous Bayesian phylogenetic approaches to explore patterns in the dynamics and spatial spread of Hendra virus. Analysis was performed on a 2015 bp intergenic region between the nucleoprotein and phosphoprotein genes. **Results**: Preliminary analysis indicates a broad spatial structure, with lineages clustering loosely in space and time. However, we also find that multiple variants co-circulate in one colony at any given time, and that identical variants may co-circulate in geographically disparate colonies. Our ongoing approach is to identify drivers in the spatial spread and diversity of Hendra virus by examining the role species composition, roost structure, and migratory behavior play in shaping the geneology of Hendra virus. **Conclusions**: These data suggest that host factors (e.g., species composition within roosts) and/or environmental factors may play a role in HeV circulation within and between bat colonies. This work represents a novel approach to understanding the transmission dynamics and evolution of Hendra virus, as well as the functional connectivity of flying fox populations in eastern Australia.

15. **Viral Zoonosis in Georgian Bats**

Tamar Kutateladze[1], Lela Urushadze[1,3], Davit Putkaradze[1], Magda Dgebuadze[1], Giorgi Babuadze[1], Ioseb Natradze[3], Lillian Orciari[2], and AndresVelasco-Villa[2]

[1] National Center for Disease Control and Public Health Lugar Center, Georgia;
[2] CDC Atlanta, USA; [3]Ilia State University, Georgia

Objectives: Bats are reservoir-hosts of viral agents (lyssaviruses, paramyxoviruses, coronaviruses, and filoviruses), which are transmittable to humans and other animals. There are few bat virus detection studies linked to the Caucasus region. In Georgia, bat *Lyssavirus* (Rabies virus) is listed as a priority pathogen, and West Caucasian Bat Virus (WCBV) is the most genetically different member of the *Lyssavirus* genus. The goal of our study was to find WCBV and the newly discovered bat Coronavirus (bat-CoV) in Georgian bats. **Methods:** Bats that were used for sampling were collected in 2012 from four different regions in Georgia. Bat brains (n=236) were sampled and tested for the presence of lyssavirus antigen by the direct fluorescent antibody (DFA) test. A total of 186 bats of 11 different species were sampled for CoV confirmation. RT-PCR amplification assay targeting the 180 bp fragment within the RNA-dependent RNA polymerase RdRp gene and sequencing of the amplified product was used to confirm the presence of coronaviruses in bat specimens. The PCR product was sequenced on an ABI 3130 Automatic Sequencer. **Results:** None of the bats had detectable antigen consistent with an active infection of related *Lyssavirus* or WCBV. We found an outstanding diversity of CoV strains in Georgia; 54 bats tested positive for CoV. Sequence analysis demonstrated 97- 99% identity to five different types of CoV available at NCBI database. Most CoV positive bats were collected from Imereti, which is located in western Georgia. Bats with a higher prevalence of CoV were *Myotis blhytii* and *Rhinolophus ferrumequinum.* **Conclusions:** Our study revealed that we need additional research for excluding the existence of WCBV in Georgian bats. Future work will include determining the prevalence of rabies virus in these bat samples. To do this, we will perform rabies virus neutralization “Rabies Vaccine Response End-Point Titer (RFFIT)” assays. This was the first study addressing the genetic diversity of bat-CoV in this region. Further analyses and interpretation of the phylogenetic results for CoV will be a benefit for surveillance, system control, and response measures of emerging pathogens in Georgia.

16. Forestalling Future Outbreaks: Enhancing Capacity for Surveillance of Viral Hemorrhagic Fever Viruses in Sierra Leone

Aiah Lebbie[1], Jonathan Towner[2], Ibrahim Bakarr[3], Brian Amman[2], Amy Schuh[2], Jonathan Johnny[3], Tara Sealy[2], James Graziano[2], Celine Taboy[2], John Klena[2], Immah Conteh[1], Stuart Nichol[2], Alusine Koroma[1], Ibrahim Foday[1]and Richard Wadsworth[1]

[1]Department of Biological Sciences, Njala University, Sierra Leone, [2]Centers for Disease Control & Prevention, Atlanta, Georgia, USA, [3]Department of Wildlife Management, Njala University, Sierra Leone

Objectives: The first outbreak of Ebola virus disease in Sierra Leone exposed the limited in-country capacity for effective disease surveillance. Heavy reliance was placed on international support for human, technical and material resources. While the source of the outbreak has not been confirmed, human interactions with wildlife and their habitats continue unabated, raising fears of future outbreaks of zoonotic diseases. Building national level capacity, especially in research universities, would enhance Sierra Leone’s capability to forestall future outbreaks involving viral pathogens of public health concern. **Methods:** Through a collaborative agreement with the Viral Special Pathogens Branch at the Centers for Disease Control & Prevention, staff and students at Njala University have received field and laboratory training in ecological surveillance and molecular diagnosis of hemorrhagic fever viruses in bat populations. **Results:** Training in safe capture techniques, collection of blood/serum samples, necropsy techniques and the safe processing and storage of tissues specimens have been achieved over a period of 18 months for 12 Njala University staff and students. Further, three additional staff and students have been trained in molecular diagnostics using robotic nucleic acid extraction and qRT-PCR methods. These trainings, coupled with the acquisition of laboratory and field equipment and renovations of laboratory space on the Njala University campus and its field research station, are resulting in the inclusion of ecological surveillance and molecular diagnostics of viral pathogens in wildlife populations in the curriculum of Njala University in Sierra Leone. **Conclusions:** Strengthening technical and human capacity for disease surveillance in bats through long-term partnerships with research institutions could lay the foundation for preventing future outbreaks of global concerns.

17. Ecological aspects of bats in a cave frequented by members of the local community in Kaptum Cave in eastern Uganda.

Matovu Benard[1] (Graduate student), Nalikka Betty[2] and Kityo Robert[3]

Makerere University, College of Natural Science – Department of Zoology, Entomology and Fisheries Science Kampala Uganda

Few studies have addressed the ecology of cave bats in Uganda. This study assessed the diversity, roosting and feeding ecology, of micro bats (order *chiroptera*) as well as influence and frequency of human disturbance, in Kaptum cave of Eastern Uganda. Field observations were conducted between July/Augst 2016 and October/ November 2016 to document aspects of roost utilisation by the bats, their feeding choices and human influences on the cave in which 6 species of microchiropteran bats roosted. We used Mist nets and a Harp trap to capture individuals for examination and identification of species present. Infrared Trail trap Cameras were used to monitor roosting habits and activity patterns of the bats in the cave. A portable whether station was used to record the microclimatic conditions in the different sections of the cave in which the bats roosted to evaluate if there was any influence on choice roost. Kaptum cave has 6 species of insectivorous bats which seemed to prefer different sections of the cave. From evidence of insect remains in the roost, the diet of the bats in Kaptum cave consisted of eight insect orders (*Lepidoptera, Coleoptera, Orthoptera, Dictyoptera, Heymenoptera, Isopteran, Hemiptera, and Odonata*) with the order *Lepidoptera* constituting the bulk of insects preyed upon. At the moment we cannot separate the diet of the different species, since most insect remains were recovered in a section the cave we refer to as the Nycteris corner, because it was most used by these bats, but other species of Rhinolophids and Hipposiderids also frequented this corner in any 24hr period. We believe that the continued human presence in the cave could have implications for roost stability, but also could predispose the humans to potentially harmful aerosols associated with bats and bat guano.

18. **Middle East respiratory syndrome coronavirus spike plasticity in the context of the common vampire bat (*Desmodus rotundus*) DPP4 receptor.**

Rebekah McMinn[1], Michael Letko[1], Neeltje van Doremalen[1], Kerri Miazgowicz[2], Vincent Munster[1]

[1]Laboratory of Virology, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health [2]Department of Infectious Diseases, College of Veterinary Medicine, University of Georgia

Objectives: In 2012, a novel coronavirus, Middle East respiratory syndrome coronavirus (MERS-CoV), was discovered in humans and dromedary camels, although genetic evidence supports a bat ancestor. This range of animal hosts lead us to hypothesize that MERS-CoV can readily adapt to new hosts. The receptor for MERS-CoV, dipeptidyl peptidase 4 (DPP4) has previously been shown to act as a species barrier. By passing the virus over time on cells stably expressing the common vampire bat (*Desmodus rotundus*) DPP4 receptor, which MERS-CoV binds inefficiently, we will determine how potential adaptation in the spike glycoprotein may influence species tropism. **Methods:** We have compared the growth kinetics of MERS-CoV over 72hrs between different bat DPP4 receptors transfected on baby hamster kidney (BHK) cells, which are naturally unsusceptible to MERS-CoV. We then generated BHK cell lines stably expressing the *D. rotundus* DPP4 receptor. By passing MERS-CoV on these cells over time, we hope to observe adaptations in the viral spike protein that allow more efficient viral growth kinetics. Viral genomes containing the relevant mutations can be created through a reverse genetics system and tested for binding affinity and growth potential. **Results:** We show here that MERS-CoV can use DPP4 from different animal hosts, including a variety of bat species. Notably, MERS-CoV can bind and replicate using the *D. rotundus* DPP4 but very inefficiently compared to human DPP4, leading to delayed growth. We observed that MERS-CoV growth on cells stably expressing D. rotundus DPP4 displays a similar inefficient growth pattern as seen previously using a transfection method. **Conclusions:** Our data demonstrates that MERS-CoV can use a diverse set of host species receptors. Although we have successfully generated BHK cells stably expressing *D. rotundus* DPP4, sequencing of the MERS-CoV spike over many passages is needed to identify relevant mutations. The ability of the MERS-CoV spike to adapt to diverse host species receptors may play a significant role in cross-species transmission.

19. **Viral community dynamics of Australian Flying foxes**

Alison J. Peel[1], Victoria Boyd[2], Raina K. Plowright[3], Olivier Restif[4], Gary Crameri[2], John Giles[1], Hamish McCallum[1], Konstans Wells[1]

[1] Environmental Futures Research Institute, Griffith University, Queensland, Australia; [2] CSIRO Australian Animal Health Laboratory (AAHL), Geelong, Victoria, Australia; [3] Montana State University, Department of Microbiology and Immunology, Bozeman, MT, USA; [4] Department of Veterinary Medicine, University of Cambridge, Cambridge, UK

Objectives: Bats are reservoirs for a disproportionate number of zoonotic viruses, with spillover to people and domestic animals resulting in significant public health implications globally. In Australia, bat viral research has largely focused on Hendra virus, yet a diverse viral community has been detected in Australian Pteropid fruit bats (flying-foxes)[1,2]. Additionally, while the four Australian flying fox are capable of being infected with Hendra virus, not all species appear to be equally competent hosts[3,4]. In this context, interactions among co-infecting viruses and the dynamical consequences of these interactions are under- studied. We aimed to gain further insight into bat viral transmission dynamics by exploring dynamics within a multi-host-multi-pathogen framework. **Methods:** To characterise existing knowledge of the bat viral-host community in Australian flying foxes, a systematic literature review of published studies was undertaken and then complimented with additional unpublished data. Using urine samples collected from three of the four Australian flying-fox species in a related field study[6], we utilised a novel high-throughput multiplex PCR[5] to simultaneously detect up to 11 known bat paramyxoviruses. Within a Bayesian framework, we then modelled the monthly presence of different virus species at the roost level in relation to environmental drivers and the co-occurrence of other virus species. **Results:** Results support synchronous shedding pulses of multiple viruses, with significant co-circulation associations between certain virus species. **Conclusions:** Natural host-virus systems comprise complex communities, and our study explores how moving beyond single-pathogen-single host studies of bat pathogen dynamics towards broader consideration of the biotic interactions within viral and reservoir communities could progress our understanding of transmission and spillover of bat pathogens.

20. **The glycoprotein of Nipah virus in Thai bats associated with Nipah virus in Bangladesh**

Ponpinit T[1], Wacharapluesadee S[1], Duengkae P[2], Kaewpom T[1], Yinsakmongkon S[3], Rodpan A[1], Hemachudha T[1]

[1] World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University, [2]Faculty of Forestry, Kasetsart University, [3]Faculty of Veterinary Medicine, Kasetsart University

Objectives Bats have been recognised as a natural reservoirs of a large number of viruses including Nipah virus (NiV) and are associated with human activities which plays important role in the transmission of pathogens from bats to human. Study the glycoprotein NiV protein which plays important role in virus entry into host cells is a crucial in order to know the virus transmission. **Methods** Bat urine were collected from Luang Phrommawat temple, Chonburi province and screened for NiV nucleocapsid by using hemi-nested RT-PCR. The NiV positive urine samples were amplified the whole glycoprotein gene (1.8 kb). The whole sequences of nucleotide and amino acid of NiV glycoprotein were compared with sequences from both Malaysian and Bangladeshi strains from bats and humans. The phylogenetic tree was constructed by comparing amino acid sequence between NiV from Thai bat and NiV Bangladeshi patient. **Results** NiV glycoprotein sequence from Thai bats were homologous with Bangladeshi strain compared to the Malaysian strain. Furthermore, it shared 99.2-100% and 99.2-99.5% identity with nucleotide sequence of NiV glycoprotein from Bangladeshi bats and Bangladeshi patients, respectively. Amino acid sequence of NiV glycoprotein from Thai bats shared 99.8-100% and 99.5-99.7% identity with Bangladeshi bats and Bangladeshi patients, respectively. While, nucleotide sequence of NiV glycoprotein in Thai bats shared only 93.0-93.3% and 93.2% identity with Malaysian bats and Malaysian patients, respectively. Like nucleotide sequence, the amino acid sequence of NiV Thai bats shared only 95.7-96.0% and 95.7% identity with Malaysian bats and Malaysian patients. Phylogenetic analysis of NiV glycoprotein amino acid revealed that the NiV glycoprotein in Thai bats belonged to Bangladeshi patients. **Conclusions** This is the first step to understand the mechanism of NiV entry to the host. The results may indicates that NiV Thai bat strain has the potential to cause infection in humans. NiV glycoprotein and host receptors should be further investigated in order to understand the viral entry mechanism, host range, including intra- and cross-species transmission. Understanding the transmission of NiV from bats to humans is crucial in order to predict and prevent NiV outbreaks.

21. **Genomic characterization and pathogenic potential of a novel evolutionarily-divergent alphacoronavirus isolated from *M. lucifigus* bats in Alaska.**

Jonathan C. Rupp[1], Maegan Lange[1], Megan Howard[2], Anitha Sundarajan[3], Jonny Sena[3], Faye D. Schilkey[3], Molly Murphy[4], Douglas Causey[1], Eric Bortz[1].

[1]Dept. of Biological Sciences, University of Alaska Anchorage; [2]Battelle Memorial Institute; [3]National Center for Genome Resources, santa Fe NM [4]Dept. of Veterinary Medicine, University of Alaska Fairbanks

Coronaviruses (CoV) are zoonotic pathogens with the potential to cross species barriers from bats into other mammals, including marine mammals, swine and humans. Novel bat-origin coronaviruses have been responsible respiratory disease in humans, notably betacoronaviruses (OC43, HKU-1, SARS and MERS) and alphacoronaviruses (229E and NL63). Thus, it is important to identify the reservoirs of CoV in bats and their potential for transmission, and pathogenicity, in other mammalian species. We sought to analyze the virome of the most common bat species in Alaska, *Myotis lucifugus,* the little brown bat. Swabs, tissue, and fecal samples were collected from habitats in close proximity to barns, farm buildings, and human habitations in southcentral Alaska. Total RNA extracts were screened by RT-PCR with coronavirus primers matching CoV ORF1a, and Sanger sequencing of amplicons confirmed the presence of an alphacoronavirus phylogentically related to persistent alphacoronaviruses detected in bats in Colorado and the Rocky Mountains. Primary RNA samples were used in library preparation for short-read, paired-end next generation sequencing on an Illumina HiSeq platform. Aligning to a reference *M. lucifigus* virus from Colorado, bat alphacoronavirus CDPHE15/USA/2006, we assembled a full-length genome (28,515nt) identifying the novel alphacoronavirus/bat/Alaska/s7/2014. A high degree of thermodynamically stable stem-loop RNA structures are predicted by Mfold within 700nt of 5' and 3' termini of genome**.** While nucleotide conservation to the Colorado virus was 96%, notable amino acid differences were identified in coronavirus proteins. The major CoV surface spike (S) protein exhibited 26 amino acid changes, including 14 in the globular head containing the putative receptor-binding domain, suggesting divergence based on immune evasion or receptor-specificity. Another 6 amino acids were altered in the fusion hinge. Protease cleavage sites were not conserved. Nucleoprotein (N) and ORF3 also exhibited amino acid differences. Understanding the evolution and pathogenicity of this novel alphacoronavirus provides insight into the role of bats in virus transmission, and ecological assessment of bat-borne virus reservoirs in North American ecosystems.

22. **Spatial pattern of genetic diversity and selection in the MHC class II DRB of three Neotropical bat species**

Salmier A., de Thoisy B., Crouau-Roy B., Lacoste V. and Lavergne A.

Host–pathogen interactions—greatly influenced by environmental characteristics—are a major determinant of the extensive polymorphism of the Major histocompatibility complex (MHC) genes that play an important role in both resistance and susceptibility to diseases. Amazonia encompasses the greatest bat richness, as well as great landscape diversity. However, there are few studies regarding adaptation to infectious diseases of bats and even less in contrasting environmental conditions. We analyzed the genetic variability and positive selection signatures of the expressed MHC class II *DRB* exon 2 in three sympatric Amazonian bat species, *Carollia perspicillata*, *Desmodus rotundus*, and *Molossus molossus* inhabiting different environments (*e.g.*, forests, edge habitats, and urban areas). The role of the environment on the allelic composition and distribution of the *DRB* gene, as well as the effects of pathogen-mediated selection, recombination, gene conversion, demographic history and population structure on the MHC diversity were investigated. Overall, we identified 23 *DRB* alleles in 19 *C. perspicillata*, 30 *DRB* alleles in 35 *D. rotundus* and 20 *DRB* alleles in 28 *M. molossus*. We found clear evidence of at least two functional *DRB* loci as well as a trans-species mode of evolution within the Phyllostomidae family. Bats inhabiting forest environments presented higher number of alleles, revealing a heterozygote advantage likely associated with higher diversity of microorganisms in forest environments due to greater host species richness and better transmission-promoting parameters compared to disturbed environments. The *DRB* polymorphism was high in all sampling sites and for all species but different signatures of positive selection were detected depending on the environment, suggesting a local adaptation characteristic driven by an area-limited pathogen-mediated selection. The patterns of *DRB* diversity were similar to those of neutral markers for *C. perspicillata* and *M. molossus* while these patterns were different for *D. rotundus* for which a geographical structure was highlighted. These results supported that demographic process acts as an additional force in shaping *DRB* diversity. However, in structured populations, environmental constraints associated with characteristic pathogen pressures are the main drivers of MHC diversity.

23. Establishing a field collection scheme to investigate the role of African fruit bats as the natural reservoir of ebolaviruses

Ken Cameron[1], **Stephanie Seifert[2]**, Shauna Milne-Price[2], Alain Ondzie[1], Trent Bushmaker[2], Jean-Vivien Mombouli[3], Sarah Olson[1] and Vincent J. Munster[2]

[1]Wildlife Conservation Society, 2300 Southern Boulevard, Bronx NY, USA2
[2]Laboratory of Virology, Virus Ecology Unit, Division of Intramural Research, National Institutes of Allergy and Infectious Diseases, National Institutes of Health, Rocky Mountain Laboratories, Hamilton, USA
[3]Laboratoire National de Santé Publique, Brazzaville, Republic of Congo

Objectives: Filoviruses are among the most well-known and well-studied zoonotic pathogens, yet we know little about filovirus populations in their natural reservoirs. Phylogeographic and population genetic studies of filoviruses isolated from their natural reservoirs would shed light on the population structure and evolutionary history of these important zoonotic pathogens. African fruit bats including *Hypsignathus monstrosus* and *Epomops franqueti*, are the candidate natural reservoirs for filoviruses in the *Ebolavirus* genus; however, there have been no successful attempts to sequence or isolate *Ebolavirus sp.* from PCR-positive bats due to low viral copy numbers in the bats and difficulty associated with sampling from wild bat populations. We sought to increase the likelihood of acquiring live virus and viral whole genome sequences through extensive sampling from wild bat species in the Odzala-Kokoua National Park, Republic of Congo, within the geographical area of previous Zaire ebolavirus outbreaks. **Methods:** Multiple capture-release studies were performed to sample fruit bats over a period of four years. Bats were captured by mist netting near an *H. monstrosus* lekking tree and sampled for whole blood in addition to collecting nasal, urogenital, and rectal swabs. **Results:** In total, samples were taken from 456 *H. monstrosus* bats and 43 *E. franqueti* bats across four years of sampling. An additional 57 samples were taken from other bat species. Preliminary serological work shows 4.9% seroprevalence against Zaire ebolavirus in a subset of the *H. monstrosus* bats. **Conclusions:** The field collection efforts have yielded a large number of bats sampled which show a history of Zaire ebolavirus exposure. Future work will focus on detecting active infection with ebolavirus and isolation of live ebolavirus for whole genome sequencing.

24. **Co-infection in Georgian Bats**

Lela Urushadze[1,3], Ying Bai[2], Lynn Osikowicz[2], Ioseb Natradze[3], Ketevan Sidamonidze[1], Davit Putkaradze[1], and Michael Kosoy[2]

National Center for Disease Control and Public Health, Tbilisi, Georgia[1]; Centers for Disease Control and Prevention, Atlanta, USA[2]; Ilia State University, Tbilisi, Georgia[3]

Objectives: Bats have been recognized as natural reservoirs for a variety of zoonotic pathogens. The prevalence of different pathogens in bats could be associated with colony size and migration patterns. In this study, bats were collected from four different Georgian regions (Kakheti, Imereti-Tskhaltubo, Samegrelo, Kvemo Kartli) and were tested for different pathogens that are endemic to Georgia. **Methods**: In total, 218 bats (*Eptesicus serotinus*-20, *Miniopterus shrebersii*-27, *Myotis blythii*-67, *Myotis emarginatus*-38, *Pipistrellus pygmaeus*-12, *Rhinolopus Euriale*-26, and *Rhinolopus ferrumequinum*-22) were tested for four bacterial agents (*Bartonella, Brucella, Leptospira,* and *Yersinia*). Bat kidneys were dissected, and their DNA was tested for *Bartonella*, and *Leptospira*. Spleen DNA was tested for *Brucella* and *Yersinia*, and the intestine DNA was tested for *Yersinia*. Triplex Real-Time PCR (rtPCR) Assay was performed to detect *Brucella* (IS711), *Bartonella* (tmRNA), and *Yersinia* (pal). Singleplex rtPCR was used to identify *Leptospira* (LipL32). Targeting the 16S rRNA gene, conventional PCR was performed to detect multiple bacterial strains. Cultured *Bartonella* isolates of the *gltA* gene were sequenced. **Results:** A total of 113 (51%) were positive for at least one of the four pathogens. Co-infection was detected in different bat species from Tskhaltubo and Kakheti. One Tskhaltubo bat was positive for *Bartonella*, *Brucella*, and *Leptospira*. Two bats from Kakheti were co-infected with *Bartonella* and *Brucella*: (*Myotisblythii* (n=1), and *Miniopterusschreibersii* (n=1). Eighteen bats were co-infected with *Bartonella* and *Leptospira*: *Myotisblythii* (n=15), and *Miniopterusschreibersii* (n=3). Sequencing analysis confirmed a co-infection with two different *Bartonella* sequences from 16 different bats: *Myotisblythii blythii* (n=3), *Miniopterusschreibersii schreibersii* (n=7), *Myotisblythii emarginatus* (n=1), *Rhinolophus euryale* (n=2), and *Rhinolophus ferrumequinum* (n=3). All bats were negative for *Yersinia*. **Conclusions:** Our results indicate that bat colonies in Tskhaltubo have the highest prevalence of infection and co-infection; since these bats are in enclosed, small spaces such as caves, this may be a reason we see a mixture of pathogens and mutation. In the past couple of years', Georgian caves have become a popular tourist attraction; from a public health standpoint, it is important to know what types of pathogens exists in these local bats.

25. Caves of Myanmar: a high-risk human-wildlife interface for zoonotic disease
Megan E. Vodzak, MS, MPH[a], Ohnmar Aung, MBBS, MA [a], Marc T. Valitutto, VMD[a], Kyaw Y. N. Tun, BVSc, MSc, PhD [a], Heather S. Davies, MS [b], Michael E. von Fricken, PhD, MPH [a,b], Suzan Murray, DVM, DACZM[a], and Dawn M. Zimmerman, DVM, MS[a]

[a] *Global Health Program, Smithsonian Conservation Biology Institute, Washington, DC, USA*
[b] *Department of Global and Community Health, George Mason University, Fairfax, VA, USA*

The Southeast Asian country of Myanmar has been deemed a “hotspot,” both in terms of its biodiversity and disease emergence potential. Despite this recognition, there is a paucity of data and limited surveillance on emerging infectious diseases in Myanmar, due in part to almost five decades of political isolation. Recent changes in the government have expanded economic development, strengthening trade with neighboring countries and opening border access to tourists and investors, further contributing to potential underlying drivers of disease emergence. Of particular import and concern are zoonotic diseases arising from human-animal contact. The vast cave and karst system of Myanmar presents an understudied interface between humans and wildlife, such as bats, rodents, and non-human primates. Caves, particularly where intricate Buddhist shrines have been installed, are popular destinations for local, national, and international visitors despite high-contact potential with animals and their excrement. This poster underscores the growing risk of bat-borne pathogen exposure in relation to cave utilization in Myanmar, exemplified by the popular tourist destination town, Hpa-An.

26. **Prevalence Patterns of Coronaviruses in Lyle's flying fox (*Pteropus lylei*) in Thailand**
Supaporn Wacharapluesadee[1], Prateep Duengkae[2], Aingorn Chaiyes[2], Sangchai Yinsakmongkon[3], Pattarapol Maneeorn[4], Patcharakiti Phengsakul[2], Wachirapon Khumbucha[2], Thongchai Kaewpom[1], Apaporn Rodpan[1], Thiravat Hemachudha[1]

[1] World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University, [2]Faculty of Forestry, Kasetsart University, [3]Faculty of Veterinary Medicine, Kasetsart University,[4]Department of National Parks, Wildlife and Plant Conservation, Thailand.

Objectives Coronavirus (CoV) surveillance in Lyle’s flying fox (*Pteropus lylei*); a medium-sized flying fox which forms large colonies high up in trees in areas close to humans and other animals, was conducted to characterize strain of CoV and determine prevalence patterns in Chonburi province, Thailand. **Methods** *P. lylei* bats were captured monthly during January - December 2012 for detection of CoV at three closed areas in Chonburi province, two human dwellings which were 0.6 (S1) and 5.5 km (S2) away from the bat roost, and a bat roosting site (S3). Two nested RT-PCR of RNA-dependent RNA polymerase (RdRp) from rectal swabs were used for CoV detection. The strain of CoV was confirmed by sequencing and phylogenetic analysis. **Results** From 390 *P. lylei* bats, 239 were male and 151 were female, while 101 were juvenile (forearm length ≤136 mm) and 289 were adult. CoVs were detected in 68 bats, 17.4% using family-wide CoV PCR but not by group C betacoronavirus assay. The positive samples were found in eight months in the year that the study was conducted, the highest in June 2012. Ten mother–pup pairs were captured. Samples from 10 mothers were negative. Rectal swabs from 9 unweaned pups were available for CoV PCR assays and three of them were positive. PCR positive pup was identified with a PCR negative mother. Phylogenetic analysis of conserved RdRp gene revealed that the detected CoVs belonged to group D betacoronavirus (n=64) and alphacoronavirus (n=4). **Conclusions** Younger bats appeared to play a more significant epidemiological role in harbouring CoV. Young age but not sex or gravidity, correlated significantly with CoV detection. CoV was found in unweaned pups whose mothers tested negative for CoV. One possible conclusion is transient shedding from mother during peri-partum to the young, may maintain the virus transmission within the population. The immune status of young and adult bats against CoV, in terms of susceptibility to infection, needs to be studied to explore this. Further study into the association of CoVs with natural hosts is necessary to understand their prevalence and maintenance patterns, to evaluate its zoonotic potential.

27. Genetically Diverse Filoviruses in *Rousettus* and *Eonycteris* spp. Bats, China, 2009 and 2015
Xing-Lou Yang[1], Yun-Zhi Zhang[1], Ren-Di Jiang[1], Hua Guo, Wei Zhang, Bei-Li, Ning Wang, Li-Wang, Cecilia Waruhiu, Ji-Hua Zhou, Shi-Yue Li, Peter Daszak, Lin-Fa Wang, Zheng-Li Shi

Bats have been implicated as natural reservoirs for filoviruses based on serological or nucleotide evidence from 19 bat species in 8 countries across Asia, Africa, and Europe. Previously, we discovered filovirus antibodies in several bat species in China. Here we report genetically divergent novel filoviruses are circulating in the *Rousettus* and *Eonycteris* bats from China. The 310-bp L-gene sequences exhibited 65–99% nucleotide (nt) identity among themselves and 61–78% nt identity with known filoviruses. Phylogenetic analysis of these sequences suggests that at least 3 distinct groups of filovirus are circulating in these bats. Q-PCR results showed these filoviruses were mainly located in the lung, with genome copy number varying from 29 to 523,582/mg of tissue. Thus, these filoviruses may have the potential to be transmitted through the respiratory tract. Co-infection with four different filoviruses was found in a single bat. ELISA and Western Blot showed the antibodies reacting more strongly to EBOV NP than RESTV NP in some filovirus RNA negative bats. One of the viruses named BtFilo9447 were tried to amplify the whole genome. The GP gene of BtFilo9447 shared 34-39% similarity on aa level and 35-53% similarity on nt level with known filoviruses. Our results demonstrate that fruit bats may are important reservoirs of filoviruses. Considering their feeding habitats, fruit bats are often in close contact with domestic animals and human populations. It is therefore necessary to establish long-term and proactive surveillance of these viruses and related diseases.

28. **Development of a monoclonal antibody to Jamaican fruit bat CD3γ**
Miles Eckley, Ann Hawkinson, Tyler Sherman, Tony Schountz, Corey L Campbell

[1]Arthropod-borne and Infectious Diseases Laboratory, Colorado State University and [2]Department of Biology, University of Northern Colorado.

Objective: T cells have critical immunomodulatory roles in the innate immune response to infection. The CD3 cell-surface protein complex is required for T cell activation, and thus treating bats with therapeutic Aj-anti-CD3 IgG antibodies may have immunosuppressive effects. Monoclonal antibodies are of particular interest for this application because of their ability to bind to the Fc receptor of phagocytic and cytotoxic cells and label a pathogen for destruction. Our goal is to investigate the biological mechanisms by which T cells may induce immunopathology in response to viral infection. **Methods**: BALB/c mice were immunized and boosted with a KLH-conjugated 30mer peptide from Jamaican fruit bat CD3γ. Hybridoma cells were produced from the fusion of splenocytes with Sp2/0-Ag14 myeloma cells. Hybridoma cells were selected and cloned on methylcellulose plates, transferred to 24 well plates and supernatants screened. Candidates were identified by ELISA to 30mer peptide conjugated to BSA first, followed by flow cytometry of bat splenocytes. Antibodies were purified from supernatants by affinity chromatography using a protein A/G agarose resin bed. Isotype determination was done by ELISA using HRP labeled mouse anti-IgM, IgG2a, IgG1 and biotin labeled rat anti- IGg2b, IgA and IgG3 primary antibodies. **Results**: Three hybridoma clones for Aj-anti-CD3 IgG were purified from the cell culture supernatants and stored for later use. Each of the three hybridoma clones are expected to have produced a different isotype based on flow cytometry data. **Conclusions**: In future work, we will use Aj-anti-CD3 antibody labelling of T cells in vivo to deplete T cells and determine whether immunopathology to Tacaribe virus, which normally causes fatal infection, will be ameliorated.

29. **Bats and Immunity: Anti-Viral IFNγ Responses Differ Among Hosts**
C. Cotter, T. Schountz, C.L. Campbell

Arthropod-borne and Infectious Diseases Laboratory, Colorado State University

Anti-viral responses in bats (order Chiroptera) is largely unknown to researchers. Although bats account for 20% of all mammal species, they are relatively understudied in the scientific community (Baker et al., 2013). Bats are reservoir hosts for zoonotic diseases such as severe acute respiratory syndrome (SARs), rabies virus, and Ebola virus (Mandl et al., 2015). Reservoir hosts, generally, do not show pathogenic signs or succumb to disease when infected with such viruses. Current efforts by Kuzmin et al to better understand anti-viral responses in Egyptian rousette bat (*Rousettus aegyptiacus*) and human cells include a comparative study of host innate immune response to infection with Ebola virus or Marburg virus. They focused on the interferon (IFN) response. Kuzmin et al. demonstrated that bat IFNγ (type II IFN response) decreased viral replication in cell culture, whereas the human IFNγ produced by the human cells did not. Additionally, IFNγ stimulated the type I IFN (IFNα/β) response Kuzmin et al., 2017). My research focuses on Jamaican fruit bat (*Artibeus jamaicensis*—Aj) IFNg and its role in an anti-viral response to New World mammarenavirus Tacaribe (TCRV). *A. jamaicensis*, when infected with

TCRV, suffer fatal infections (Cogswell-Hawkinson, 2012). Most arenaviruses, TCRV excluded, produce a nuclear protein (NP) that blocks the type I IFN response at interferon response factor-3 (IRF-3) (Martinez-Sobrido et al., 2007). Pathogenesis of TCRV is still unknown; however I hypothesize that it interferes with the IFN response pathway by a different mechanism. Therefore, introduction of therapeutic Aj IFNγ to TCRV infected A. jamaicensis should be able to stimulate an appropriate, anti-viral innate immune response to rescue them from death. My project focuses on cloning, expressing, and purifying Aj IFNγ in order to synthesize a recombinant antibody for Aj IFNγ.

30. **Virome analysis of neotropical bats on the Caribbean island of Trinidad**

[1] Department of Preclinical Sciences, Faculty of Medical Sciences, The University of the West Indies, St Augustine, Trinidad and Tobago; [2] Center for Infection and Immunity, Mailman School of Public Health, Columbia University, New York, USA; [3] School of Veterinary Medicine, Faculty of Medical Sciences, The University of the West Indies, St. Augustine, Trinidad and Tobago

Objectives: Bats are recognized as reservoirs for a number of important zoonotic viruses. The Caribbean island of Trinidad is richly diverse in bat fauna with 68 species recognized. Viruses detected in Trinidad bats include Rabies virus, Tacaribe virus, Rio Bravo virus, Tamana bat virus and more recently a bat coronavirus. The objective of this study was to identify and characterize known and novel viruses in Trinidad bat species. **Methods:** During the period 2012- 2016, bats were sampled from 19 locations in Trinidad. The novel virome capture sequencing platform for vertebrate viruses (VirCapSeq-VERT) was employed to sequence faecal swab samples from 73 bats belonging to seven neotropical species (*Desmodus rotundus, Carollia perspicillita, Uroderma bilobatum, Molossus molossus, Molossus rufus, Pteronotus parnellii* and *Artibeus spp*). Sequence reads were processed using the bioinformatics pipeline at Center for Infection and Immunity to remove host background and assemble contigs that were then subjected to homology search using MegaBlast against the GenBank nucleotide database. Sequences that showed poor or no homology at the nucleotide level were searched against the GenBank viral protein database using BLASTx. The bat fecal samples were also screened by consensus PCR for 8 viral families (*Arenaviridae*, *Herpesviridae*, *Coronaviridae*, *Orthomyxoviridae*, *Alphaviridae*, *Flaviviridae*, *Rhabdoviridae*, *Picornaviridae*) using broadly reactive degenerate primers as outlined in the laboratory protocol for the PREDICT II surveillance project. All PCR products were confirmed by sequencing. **Results:** Consensus PCR detected sequences of Herpesviridae (bat herpesviruses) and Coronaviridae (bat coronaviruses). Preliminary analysis of VirCapSeq-VERT data provided evidence of both known and potentially novel viruses, the majority of which belonged to the families *Anelloviridae*, *Herpesviridae*, *Coronaviridae*, *Orthomyxoviridae*, *Parvoviridae*, *Rhabdoviridae* and *Retroviridae*. The *Anelloviridae* and *Herpesviridae* were detected primarily in fruit bats. The *Orthomyxoviridae* family included Influenza A viruses and were identified in *Desmodus* and *Molossus* species. *Parvoviridae* were overwhelmingly from *Desmodus* and *Artibeus* bats from one trapping site within the same year. *Rhaboviridae* viruses were detected in Desmodus bats sampled from various locations throughout the sampling period. The Retroviridae were primarily previously described bat endogenous retroviruses. **Conclusions:** Our results indicate the presence of a wide range of both known and novel viruses in faeces from Trinidad bats. The limited identification of viruses by consensus PCR as compared to the deep sequencing technique implies that viral detection is more efficient by targeted deep sequencing. Further analysis including targeted PCR and sequencing to assemble full genomes is required to further characterise the viruses detected. Analysis of other tissues will be required to distinguish between bat viral infections and viruses associated with animal prey.

31. **Delineating the phenotype and function of major lymphocyte populations in the fruit-eating bat, Pteropus Alecto.**

Periasamy P.[1,2], Martínez Gómez J.M.[1,2], Wang LF[3] , and Alonso S.[1,2]

[1]Department of Microbiology and Immunology, [2]Immunology Programme, Yong Loo Lin School of Medicine, Life Sciences Institute, National University of Singapore, Singapore. [3]DUKE-NUS, Singapore.

Objective: The unique ability of bats to act as reservoir for viruses that are highly pathogenic to humans suggests unique properties and functional characteristics of their immune system. However, the lack of bat specific reagents, in particular antibodies, has limited our knowledge of bat's immunity. **Methods and Results**: Here, using cross-reactive antibodies, we report the phenotypic and functional characterization of CD3+ T cell subsets, CD19+ B and NK1.1+ NK cells in the fruit-eating bat Pteropus alecto. Our findings indicate the predominance of CD8+ T cells in the spleen from wild-caught bats that may reflect either the presence of viruses in this organ or predominance of these cells at steady state. In addition, bone marrow of the bat contains over 30% T lymphocytes. This is significantly greater when compared to the T cell percentages in human and mouse bone marrow which ranges between 4% and 8%. Uniquely, a significant proportion of CD3+ T cells in bat spleen constitutively express IL-17A, IL-22 and TGF- at the mRNA level. Hence, the spleen may contain a substantial population of naïve T cells that are programmed to readily differentiate into TH17 cells or Tregs. Furthermore, mitogenic stimulation induced proliferation of bat immune cells and production of cytolytic molecules granzyme and perforin, and cytokines IL-2, IL-10, TNF and IFN. Additionally, we also demonstrate B cell function via calcium flux assay. **Conclusions**: This work paves the way towards a better understanding of bat's immunity that may offer new perspectives of therapeutic interventions for humans.

32. **Seasonal serological signals in viral infections for Madagascar fruit bats**

Cara E. Brook[1], Hafaliana C. Ranaivoson[2], Christopher C. Broder[3], Andrew A. Cunningham[4], Andrea L. Graham[1], Jean-Michel Héraud[2], Louise Wong[4], James L.N. Wood[5], Andrew P. Dobson[1*], C. Jessica E. Metcalf[1*]

[1]Department of Ecology and Evolutionary Biology, Princeton University; [2]Virology Unit, Institut Pasteur of Madagascar; [3]Department of Microbiology and Immunology, Uniformed Services University; [4]Institute of Zoology; Zoological Society of London; [5]Department of Veterinary Medicine; University of Cambridge;
*These senior authors contributed equally to this work.

Objectives: Considerable evidence supports a seasonal driver of bat-borne zoonoses, with most spillover events aligned with the synchronous reproductive season of the bat host in question. Previous modeling work proposes three possible mechanisms which could underpin such seasonality: classic Susceptible-Infectious-Recovered (SIR) dynamics with a seasonal influx of naïve juveniles, Susceptible-Infected-Recovered-Susceptible (SIRS) dynamics with periodic, waning immunity, and Susceptible-Infectious-Latent-Infectious (SILI) dynamics, by which hosts maintain virus persistently but shed seasonally. We fit variations on these contrasting dynamic models to age-seroprevalence data for henipavirus infections in Madagascar fruit bats in order to test these hypotheses. **Methods:** We live-captured, serum-sampled, and extracted lower premolar teeth (under anesthesia) from 340 Madagascan fruit bats (Eidolon dupreanum) over an eighteen-month seasonal trajectory. Serum samples were subjected to Luminex assay for henipavirus antibodies, and teeth underwent histological processing to quantify bat age, resulting in the construction of age-serprevalence curves for heniapivrus exposure in E. dupreanum. We fit variations on SI, SIR, SIS, and SIRS compartmental models to these data and used generalized additive models (GAMs) to investigate seasonal variation in antibody titers for both sexes, including several individuals recaptured across our time series. **Results:** Seroprevalence to henipavirus increased with age across the early years of life in our dataset, then declined to zero in later life. Field data were best fit by either frequency-dependent transmission models incorporating infection-induced mortality or by density-dependent transmission models, allowing for rapid waning of immunity. GAM analysis of seasonal trends showed significant seasonality in an animal's serostatus, corresponding to the nutritional calendar for male bats and the reproductive calendar for female bats. Recaptured individuals demonstrated considerable dynamism in antibody titers, changing serostatus in both directions across our time series. **Conclusions:** Our analyses suggest that henipavirus infections in E. dupreanum fruit bats are governed by highly dynamic transmission mechanisms, involving rapidly waning immunity and seasonal peaks and troughs in infection status. We reject a classic SIR model in favor of a more flexible SIRS or SILI model underpinning viral transmission among bat hosts in our system. More fine-scale field data will be needed to further parse remaining hypotheses.

Thank you, Ben. My boarding passes are attached as a single PDF (two passes).

Will I need to pay the driver? If so, can it be done with my credit card? If not, I will need to get currency exchange and need to know how much it will cost.

Hi Dr Schountz,

Your flight will be on tomorrow morning at 9:35?

I will be at th hotel at 6:30. I will meet you at the hotel lobby then and ask a vehicle to send you to the airport.

Please also send me your boarding pass and I will print it for you and give you tomorrow morning.

Best

Ben

BOARDING PASS

ANA | A STAR ALLIANCE MEMBER

SCHOUNTZ/WILLIAM ANTONE

DATE	23OCT2018
FROM	WUHAN
TO	TOKYO(NARITA)
DEP TIME	09:35

ECONOMY CLASS

Y

UA*S
GYH13508 accepted

FLIGHT	GATE	BOARDING TIME	SEAT
NH 0938		09:00	24A

API ETKT 01671124838503 022

Note: Please confirm the latest information on boarding gates and times at the departure airport.

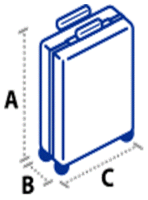
[Information for an ANA-operated flight]

[If Checking In Baggage]
Please arrive at the check-in counter at least one hour before the departure time (or at least 40 minutes before the departure time for an international flight from Haneda Airport).
When connecting to an international flight from a Japan domestic flight, please arrive at the domestic check-in counter at least 30 minutes before the departure time of the domestic flight.

[Boarding]
Please arrive at the gate at least 10 minutes before the departure time.There is a possibility that passengers who do not arrive at the gate by this time may not be able to board the flight.
When boarding a Japan domestic flight, please pass through the airport security check at least 15 minutes before the departure time.

[Required Travel Documents]
Passengers must have valid passports, visas, and other applicable travel documents ready. Travel documents will be checked at the check-in counter and boarding gate.

[Carry-on Baggage]
For international flights, each passenger may bring on board one piece of carry-on baggage in addition to one personal item.
Carry-on baggage must weigh 10 kg or less and be within the following dimensions: 55 cm x 40 cm x 25 cm (total linear dimensions cannot exceed 115 cm).
(Size restrictions may vary depending on the type of aircraft that the flight is operated with.)



A+B+C ≦ 115cm(45inch)

Note: Check-in guidelines may vary for codeshare flights. For details, please contact the operating carrier directly.

Subject: Re: Requesting invitation letter for visa application

Hi Ben,

I am happy to provide the letters. Can you help me by providing the names and address(es) of the four individuals? I'm not in my office today so that would be very helpful for me. Something like this for each of you:

Ben Hu, Ph.D
Research Assistant
Wuhan Institute of Virology
Chinese Academy of Science
Xiao Hong Shan No.44,Wu Han,P.R.China.
Postcode:430071

If you provide this information for all four attendees then I can copy and paste them into each of the four letters that I will email to you.

Thanks,

Tony

Subject: Requesting invitation letter for visa application

Dear Dr.Schountz:
I am a researcher at Wuhan Institute of Virology, Chinese Academy of Sciences. My colleagues and I are studying bat viruses and we have submitted four abstracts to the 2nd International Symposium on Infectious Diseases of Bats which is going to be held in Fort Collins in June.
The title for the 4 abstracts are:
1) SARS coronavirus may have originated from frequent recombination events betwwen SARS-like coronaviruses in a single horseshoe bat habitat (oral)
2) Dampening of STING-dependent IFN production: an implication of virus tolerance in bats? (oral) （I noticed from the web that this abstract has already been confirmed as oral presentation)
3) Genomic characterization of diverse BatCoV HKU10 and three novel alphacoronaviruses (poster)
4) Genetically diverse filoviruses in Rousettus and Eonycteris spp. bats, China, 2009 and 2015. (poster)
As it is a unique conference specializing on our research area, we are very eager to attend. However, it usually takes at least two months for us to get the US visa due to the complicated procedure of applying for travel permit to Chinese Academy of Sciences and then one month of administrative processing by US embassy. So in order we can make our visit to Colorado in late June, we have to start the process of travel permit and visa application now.
To apply for a travel permit, we are required to submit an invitation letter from the conference organizer. I know for the bat-borne disease meeting, we will know the results of the acceptance of the abstract by May. But it will be late for us to apply for the travel permit and US visa.
Could you please kindly provides four invitation letters to us indicating we will attend the meeting and give presentations? (oral or posters)
It does not matter whether the abstracts will be finally selected as he invitation letters are only for visa application.
We deeply appreciate your understanding and assistance.
Thank you very much!
Best regards

Ben Hu Ph.D
Research Assistant
Wuhan Institute of Virology, CAS

Greg and Tony,
I wasn't able to work on this much tonight. I'll pick it up tomorrow afternoon and will have you something by the end of the day.

I did get a letter of support from Vincent - just waiting for a signed copy.

Cheers,
Jon

<C06 Update 2020.docx>

Pathogens transmitted by bat and arthropod vectors continue to burden the health of humans around the world. Bat-associated pathogens, such as the currently circulating SARS-CoV-2, ebolaviruses, Nipah virus, rabies virus and others are among the most impactful and dreaded infections known. Malaria is perhaps the most deadly infection in the tropics. West Nile, chikungunya and Zika viruses have emerged as major global pathogens. Tick-transmitted infections such as Lyme disease and Powassan virus continue to emerge in temperate regions. Agents vectored by bat and/or arthropod vectors thus constitute some of the most feared, difficult and persistent problems affecting human health.

Therefore, Colorado State University (CSU) established the Arthropod-borne and Infectious Disease Laboratory (AIDL) in 1984 to counter these emerging threats. One of the many unique aspects of AIDL includes housing one of the only captive breeding colonies of bats for use in infectious disease research, and BSL2 and BSL3 insectaries. The pandemic spread of SARS-CoV-2 highlights the national need for this unique resource, and the central role that CSU now occupies in the ability of the US to study and design countermeasures against emerging viral threats of this type.

Commented [S1]: This seems out of place in the context of bats (before) and SARS-CoV-2 (after).

To support research into emerging diseases, CSU committed $22M in 2019 to construct a new building, the Center for Vector-Borne Infectious Diseases (CVID), to replace aging AIDL infrastructure. CVID construction is ongoing and we anticipate moving in in late 2020.

While CSU's commitment of $22M is laudable, it is insufficient to provide adequate housing for the additional bat colonies needed to address the urgent need for research into the biology and emergence of SARS-CoV-2. Further, additional infrastructure within the CVID is required in order to ensure that research focusing on bat-borne diseases is paired with adequate BSL2 lab, tissue culture and other support space.

This proposal, reviewed highly favorably in 2019 but not selected for funding, represents a unique opportunity to rapidly increase US capacity for housing, breeding and using bats in research. In particular, we propose to:

Current Bat Research at CSU

Colorado State University has a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*), one of the most common and largest bats in the New World. This colony was established in 2005 with funds from the NIAID Emerging Virus Disease Unit contract (AI25489) after it was determined that SARS-CoV was a bat-borne virus. Currently funded bat projects are to study SARS-CoV (CSU VPR funding), MERS-CoV (AI140442), bat influenza A viruses (AI134768), henipaviruses (DARPA G228-19-W7329) and rabies virus (DOE B634747). Our long-term goal for this colony is to make it the "bat version" of the laboratory mouse so that we can conduct experimental infections for other researchers, or provide bats to those who may need them for experiments at their institutions.

We have determined the species is susceptible to several viruses, including Zika virus (30716104), H18N11 bat influenza A virus (31527796), Middle East respiratory coronavirus (MERS-CoV) (26899616), Cedar henipavirus (unpublished), Tacaribe virus (22379103) and Bukakata virus (unpublished), the last two of which cause fatal diseases in the bats. We have also established primary cell lines from the species that are susceptible to MERS-CoV

(26899616), Zaire ebolavirus (27354372), and Nipah, Hendra and Cedar henipaviruses (unpublished). We have generated a number of reagents, including monoclonal antibodies and recombinant cytokines, virological and immunological methods, large transcriptome data sets (23166587, 28959737), basic physiological parameters (32164795) and we have demonstrated that it can serve as a surrogate bat model organism for the study of bat-borne viruses. Importantly, a genome assembly to 30x coverage is available (NCBI PVKR01).

SARS-CoV Project. We performed an initial susceptibility study of three Jamaican fruit bats and found that all had low levels of viral RNA in oral swabs within a few days after intranasal inoculation. By day 14, all three bats had seroconverted by ELISA to recombinant SARS-CoV-2 nucleoprotein and by day 24 the titers had increased at least 4-fold for each bat. Thus we are confident that we have established a surrogate bat model for the study of SARS-CoV-2 in bats. We currently have 27 bats enrolled in a challenge and transmission study and are performing serial euthanasia to determine virus kinetics, tissue tropism, host response and transmission dynamics.

Subject: Tenure track position at Wadsworth Center
Attachment(s): "Wadsworth Center Recuitment ad.docx"

Dear colleagues,

Please find attached a new position at the Wadsworth Center that may be relevant to you or your students. Please pass along to anyone who may be interested.

Thanks,

Tony

Tony Schountz, PhD
Associate Professor
Arthropod-borne and Infectious Disease Laboratory
Department of Microbiology, Immunology and Pathology
College of Veterinary Medicine

NEW YORK STATE | Department of Health | Wadsworth Center

Tenure-Track Position at the Wadsworth Center

Host Response to Zoonotic and Vector-borne Diseases

The Wadsworth Center is seeking an outstanding scientist at the Assistant or Associate Professor level to establish a competitive, grant-funded research program in the area of the host response to Vector-Borne Zoonotic Diseases. Areas of particular interest include responses to tick- or mosquito-borne pathogens. The focus may include innate recognition of such pathogens, elucidating the protective mechanisms of the immune response and/or development of novel diagnostics and vaccines. Candidates using a systems biology approach are also encouraged to apply.

The Wadsworth Center located in Albany, NY, is the country's most comprehensive state public health laboratory, with a staff of 700, that includes over 100 doctoral level scientists. The Center provides a dynamic research atmosphere focused on infectious, genetic, and environmental diseases and their impact on human health.

The incumbent will join a vibrant group of research scientists and epidemiologists that participate in the Center's Zoonotic and Vector-borne Diseases research focus area. Established research programs include immune evasion and pathogenesis of Lyme disease *Borreliae*, host and vector factors that determine competence of arboviruses, antibody-mediated protection against infectious agents and population genetics of *Anopheles*. Complementary Wadsworth Center research activities can be found at www.wadsworth.org.

Successful applicants will receive a competitive start-up package and access to the Center's outstanding scientific cores, a BSL2/3 insectary and AAALAC accredited BSL2/3 animal space. Teaching opportunities are available through faculty appointments in the Wadsworth Center Masters of Laboratory Science program and the University at Albany Department of Biomedical Sciences, School of Public Health.

Ph.D. degree or equivalent and relevant postdoctoral research experience required. Applicants should submit their curriculum vitae, research plan and contact information for at least three references to wcphgc@health.ny.gov referencing "Host Response" in the subject line. Applications will be accepted until December 15, 2017. AA/EOE.

Subject: Thank you!

Dear Zhengli,

I want to thank you for the invitation to speak at the emerging infectious disease conference. It was a really great experience for me and I was pleased with the talks, posters and how well your team organized and ran the meeting. I hope I can return to the next meeting in two years as I am sure we will have much more data on bats and influenza virus, MERS-CoV and henipaviruses.

I was so struck by the work at the Wuhan Institute of Virology that I spoke briefly to Peng about how your institute and our Arthropod-borne and Infectious Disease Laboratory (AIDL, http://csu-cvmbs.colostate.edu/academics/mip/aidl/Pages/default.aspx) group have so many similarities. I wonder if you might have an interest in forming a loose association between our groups? I don't know how we could manage this, but one feature I envision would be collaboration on relevant projects (e.g., arboviruses and bat-borne viruses) and training of students. So, if you think there might be interest amongst your group, perhaps we can have further discussions about it.

Thank you very much!

Tony

Terms and Conditions

1) PTE hereby awards a cost reimbursable subaward, as described above, to SUBRECIPIENT. The Budget and Scope of Work for this subaward are shown in Attachments 5 and 5A. In its performance of subaward work, SUBRECIPIENT shall be an independent entity and not an employee or agent of PTE.
2) PTE shall reimburse SUBRECIPIENT not more often than monthly for allowable costs.
3) All invoices shall be submitted using SUBRECIPIENT's standard invoice, but at a minimum shall include current and cumulative costs (including cost sharing), subaward number, and certification as to truth and accuracy of the invoice as required in 2 CFR 200.415 . Invoices that do not reference PTE's subaward number shall be returned to SUBRECIPIENT. Invoices and questions concerning invoice receipt or payment should be directed to the appropriate party's Financial Contact, as shown in Attachment 3 and detailed in Attachment 6.
4) A final statement of cumulative costs incurred, including cost sharing, marked "FINAL", must be submitted to PTE's Financial Contact NOT LATER THAN forty-five (45) days after subaward end date. The final statement of costs shall constitute SUBRECIPIENT's final financial report.
5) All payments shall be considered provisional and subject to adjustment within the total estimated cost in the event such adjustment is necessary as a result of an adverse audit finding against the SUBRECIPIENT.
6) PTE reserves the right to reject an invoice, in accordance with 2 CFR 200.305.
7) Matters concerning the technical performance of this subaward should be directed to the appropriate party's Principal Investigator, as shown in Attachment 3.
8) Matters concerning the request or negotiation of any changes in the terms, conditions, or amounts cited in this subaward agreement, and any changes requiring prior approval, should be directed to the appropriate party's Administrative Contact, as shown in Attachment 3. Any such changes made to this subaward agreement require the written approval of each party's Authorized Official, as shown in Attachment 3.
9) Substantive changes (for example, change in Scope of Work, Attachment 5A) made to this subaward agreement require the written approval of each party's Authorized Official as shown in Attachment 3. The PTE may issue non-substantive changes to the Period of Performance Bilaterally.
10) Each party shall be responsible for its negligent acts or omissions and the negligent acts or omissions of its employees, officers, or directors, to the extent allowed by law.
11) Either party may terminate this agreement with thirty (30) days written notice to the appropriate party's Administrative Contact, as shown in Attachment 3. PTE shall pay SUBRECIPIENT for termination costs as allowable under Uniform Guidance, 2 CFR 200, or 45 CFR Part 75 Appendix IX, "Principles for Determining Costs Applicable to Research & Development under Grants and Contracts with Hospitals," if applicable. If the PTE Awarding Agency suspends or terminates the prime award in whole or in part, PTE may suspend or terminate this subaward accordingly.
12) No-cost extensions require the approval of the PTE. Any requests for a no-cost extension should be addressed to and received by the Administrative Contact, as shown in Attachment 3, not less than thirty (30) days prior to the desired effective date of the requested change.
13) The subaward is subject to the terms and conditions of the PTE Award and other special terms and conditions, as identified in Attachment 2.
14) By signing below SUBRECIPIENT makes the certifications and assurances shown in Attachments 1 and 2.

By an Authorized Official of Montana State University		By an Authorized Official of SUBRECIPIENT	
Dale Huls Signature	5/30/2019 Date	Signature Ashley Stahle cn=Ashley Stahle, o=Colorado State University, ou=Sponsored Programs, email=ashley.stahle@colostate.edu, c=US 2019.05.30 15:03:14 -06'00'	Date

OSP Ref W7329-G19-228			

By signing the Subaward Agreement, the authorized official of SUBRECIPIENT certifies, to the best of his/her knowledge and belief, that:

Certification Regarding Lobbying

1) No Federal appropriated funds have been paid or will be paid, by or on behalf of the SUBRECIPIENT, to any person for influencing or attempting to influence an officer or employee of any agency, a Member of Congress, an officer or employee of Congress, or an employee of a Member of Congress in connection with the awarding of any Federal contract, the making of any Federal grant, the making of any Federal loan, the entering into of any cooperative agreement, and the extension, continuation, renewal, amendment, or modification of any Federal contract, grant, loan, or cooperative agreement.

2) If any funds other than Federal appropriated funds have been paid or will be paid to any person for influencing or intending to influence an officer or employee of any agency, a Member of Congress, an officer or employee of Congress, or an employee of a Member of Congress in connection with this Federal contract, grant, loan, or cooperative agreement, the SUBRECIPIENT shall complete and submit Standard Form -LLL, "Disclosure Form to Report Lobbying," to the PASS-THROUGH ENTITY.

3) The SUBRECIPIENT shall require that the language of this certification be included in the award documents for all subawards at all tiers (including subcontracts, subgrants, and contracts under grants, loans, and cooperative agreements) and that all subrecipients shall certify and disclose accordingly.

This certification is a material representation of fact upon which reliance was placed when this transaction was made or entered into. Submission of this certification is a prerequisite for making or entering into this transaction imposed by section 1352, title 31, U. S. Code. Any person who fails to file the required certification shall be subject to a civil penalty of not less than $10,000 and not more than $100,000 for each such failure.

Debarment, Suspension, and Other Responsibility Matters

SUBRECIPIENT certifies by signing this Subaward Agreement that neither it nor its principals are presently debarred, suspended, proposed for debarment, declared ineligible, or voluntarily excluded from participation in this transaction by any federal department or agency.

Audit and Access to Records

Subrecipient certifies by signing this Subaward Agreement that it complies with the Uniform Guidance, will provide notice of the completion of required audits and any adverse findings which impact this subaward as required by parts 200.501- 200.521, and will provide access to records as required by parts 200.336, 200.337, and 200.201 as applicable.

See Copy of Award Notice Attachment 2A.

Special Terms and Conditions:

1. Copyrights
   SUBRECIPIENT grants to PASS-THROUGH ENTITY (PTE) an irrevocable, royalty-free, nontransferable, non-exclusive right and license to use, reproduce, make derivative works, display, and perform publicly any copyrights or copyrighted material (including any computer software and its documentation and/or databases) first developed and delivered under this Agreement solely for the purpose of and only to the extent required to meet PTE's obligations to the Federal Government under its Prime Award.
2. Data Rights
   SUBRECIPIENT grants to PTE the right to use data created in the performance of this Agreement solely for the purpose of and only to the extent required to meet PTE's obligations to the Federal Government under its Prime Award.
3. Carry Forward
   Carry Forward requests must be sent to PTE's Authorized Official contact, as shown in Attachment 3.

Additional Special Terms: See Copy of Award Notice Attachment 2A.

RESEARCH COOPERATIVE AGREEMENT SCHEDULE

1. **Agreement Number**: **D18AC00031**

2. **Recipient Name:** **Montana State University - Bozeman**
307 Montana Hall
Bozeman, MT 59717

3. **Identification Numbers**:

Tax Identification Number (TIN)**: 81-6010045**

Data Universal Numbering System (DUNS) Number**: 625447982**

Commercial and Government Entity (CAGE) Code**: 1KQE9**

Federal Interagency Code for Education (FICE)**: 002532**

Catalog of Federal Domestic Assistance (CFDA): **12.910 – Research and Technology Development**

ASAP Recipient Number: **3034514**

Defense Advanced Research Projects Agency (DARPA) MIPR Number(s)**: HR0011836358**

4. **Principal Investigator/Key Personnel**: Dr. Raina Plowright
111A Lewis Hall
P.O. Box 173520
Bozeman, MT 59717-3520

Telephone:
E-mail address:

5. **Statement of Work:** The research to be accomplished is identified in the Recipient's Statement of Work and is incorporated in full text as part of this agreement. The revised budget proposal entitled "Preventing emergence and spillover of bat pathogens in high-risk global hotspots" dated 07/18/2018 and revised technical proposal dated 07/17/2018, submitted in response to Broad Agency Announcement DARPA-BAA- HR001118S0017 are incorporated by reference herein.

8. **Period of Performance Profile:**

a.	**Base Phase I (24 Months):**	**(10/01/2018 through 09/30/2020)**	**$6,296,068.00**
b.	**Optional Phase II (18 Months):**	**(10/01/2020 through 03/31/2022)**	**$1,943,433.00 (If funded)**
c.	**Total Award Amount:**		**$8,239,511.00**

9. **Funding:** The following funds are allotted to this cooperative agreement.

FY2018/2019:	$2,719,770.00 (MIPR# HR0011836358)
Total:	$2,719,770.00

10. **Appropriation Data:** Pursuant to this action:

MIPR# HR0011836358 $2,719,770.00
Account Assignment: K G/L Account: 6100.411C0
Business Area: D000 Commitment Item: 411C00
Cost Center: DS68694000 Functional Area:
DNPAQ0000.000000 Fund: XXXD4529NP Fund Center:
DS68694000 Project/WBS: DR.F3BN8.DPBX6358 PR Acct
Assign: 01

11. **Terms and Conditions:** This cooperative agreement is subject to General Terms and Conditions for Cooperative Agreements set forth in the attached Exhibit A and to any Special Terms and Conditions contained in Item 17 of this Research Cooperative Agreement Schedule.

12. **Acceptance of Cooperative Agreement:** Acceptance of this cooperative agreement is pursuant to Article 14 of Exhibit A. The Recipient is not required to countersign the Cooperative Agreement document; however, the Recipient agrees to the conditions specified in the Research Cooperative Agreement Schedule and the Articles herein unless notice of disagreement is furnished to the Agreements Officer within 15 calendar days after the date of the Agreements Officer's signature. In case of disagreement, the Recipient shall not assess the Cooperative Agreement of any costs of the research unless and until such disagreement(s) is/are resolved.

13. **Payments:** Payments will be made in accordance with Article 3 of Exhibit A.

14. **Reporting Requirements:** A final DD Form 882 is required to be filed listing all subject inventions or stating that there were none. In accordance with DARPA-BAA-HR001118S0017, the frequency of the reporting requirement differs from those commonly found in financial assistance agreements due to significant Government involvement throughout the duration of the research cycle. The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 30 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 30 days of the end of each month	See Exhibit A Attachment 2
Special Technical Report	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2019 29 Dec 2020	AOR, AO, PM, ONR & DARPA Research Services
Final Technical Report	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	28 Jan 2021	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

If Optional Phase II is implemented - The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 30 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 30 days of the end of each month	See Exhibit A Attachment 2
Special Technical Reports	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2021	AOR, AO, PM, ONR, & DARPA Research Services
Final Technical Report	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	29 JUL 2022	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

15. **Substantial Involvement:** Substantial involvement is expected between the U. S. Government and the Recipient when carrying out the activity contemplated in this Agreement.

    Substantial Government involvement will include:

    a. DARPA review and approval required after completion of one phase of the project to move on to the next phase

b. DARPA monitoring of the work with the potential of redirecting work because of interrelationships with other projects
c. DARPA review and collaboration in the development of research and analyses protocols necessary to complete the work

16. Funding Increments and Options: The Government's obligation to provide funding for increments and/or options is pursuant to Article 16 of Exhibit A.

17. Special Terms and Conditions:

a. Assurance by University to adhere to the Defense Advanced Research Agency's (DARPA) policy and communication on Dual Use of Research Concerns (DURC).

i. Definitions:

1. "Dual use research" is research conducted for legitimate purposes that generates knowledge, information, technologies, and/or products that can be utilized for benevolent or harmful purposes.
2. "Dual use research of concern," or "DURC," is life sciences research that, based on current understanding, can be reasonably anticipated to provide knowledge, information, products, or technologies that could be directly misapplied to pose a significant threat with broad potential consequences to public health and safety, agricultural crops and other plants, animals, the environment, materiel, or national security.

ii. DURC Policy: Any data with potential dual use of research concerns emerging from DARPA funded research shall be evaluated by the team, communicated to DARPA, and submitted for evaluation by team's Institutional Review Entity (IRE). If the IRE and DARPA determine that results or information obtained during the course of funded effort could be considered DURC, the IRE and DARPA will jointly determine an acceptable risk mitigation plan including a responsible publication strategy to determine appropriate venues and content that can and should be released to the public.

iii. Reporting Process: The principal investigator (PI) shall collect information about team's activities (including experiments, data collection, and data processing) on any emergent issues of relevance to DURC and GOF, and send a brief monthly report to DARPA (including negative responses). Within 15 days of a notification of a potential DURC issue the PI shall submit the findings to team's Institutional Review Entity (IRE). If the IRE determines that the findings in question are not of concern, the reported findings are not subject to additional review or oversight, but future activities must continue to be assessed by the PI in monthly reports. If IRE determines the findings could be considered DURC, the PI shall notify DARPA within 10 days of IRE's assessment along with a copy of the assessment.

b. This research **DOES NOT** require the use of Human Subjects.
c. This research **DOES** require the use of Animal Subjects. See Article 15 of Exhibit A. **No animal studies may be conducted using funds from this award until Institutional Animal Care and Use Committee (IACUC) and DARPA second level review approvals are received.**

IACUC Protocol #: Pending Approval — Expiration Date: Pending Approval
Second-level Review #: Pending Approval — Renewal due date: Pending Approval

d. This research **DOES NOT** have restricted data rights.

THIS ACTION IS MADE ON BEHALF OF A DoD CUSTOMER UTILIZING DoD FUNDS.

Exhibit A: General Terms and Conditions
Attachment 1: Quarterly Status Report Template
Attachment 2: Monthly Financial Detail Spreadsheet Example
Attachment 3: Revised Statement of Work, dated 17 Jul 2018

EXHIBIT A

JULY 2018
DARPA AGENCY SPECIFIC TERMS AND CONDITIONS

This award is subject to the DoD Research and Development (R&D) general terms and conditions, which can be found at https://www.onr.navy.mil/Contracts-Grants/submit-proposal/grants-proposal/grants-terms-conditions.aspx under the header "DoD Research and Development General Terms and Conditions," dated July, 2018 and are incorporated herein. The DARPA Agency Specific Terms and Conditions supplement the DoD Research and Development general terms and conditions. This document addresses agency-specific concerns in addition to the above referenced regulations. Award recipients (hereafter, recipient) are accountable for all applicable statutory and regulatory requirements that govern these awards, even if not specifically listed in this document or documents referenced herein.

ORDER OF PRECEDENCE

Any inconsistencies in the requirements of this award shall be resolved in the following order:

- Federal statutes
- Federal regulations
- 2 CFR part 200, as modified and supplemented by DoD's interim implementation found in 2 CFR part 1103
- Award-specific terms and conditions (DARPA Agency Specific terms and conditions)
- DoD Research and Development general terms and conditions

In case of disagreement with any requirements of this award, the Recipient shall contact the Agreements Officer listed in the award document in order to resolve the issue. The Recipient shall not assess any costs to the award or accept any payments until the issue is resolved.

1. Research Responsibility
2. Amendment of Cooperative Agreement
3. Payments
4. Prior Approvals
5. Reports
6. Public Release or Dissemination of Information
7. Acknowledgment of Sponsorship
8. Intellectual Property Matters
9. Activities Abroad
10. Security
11. Research Involving Recombinant DNA Molecules
12. Restrictions on Printing
13. Prohibition on Awarding to Entities that Require Certain Internal Confidentiality Agreements
14. Acceptance and Amendment of Cooperative Agreement
15. Live Organisms – Human and Animal Subjects
16. Funding Increments and/or Options
17. Delegation of Administrative Duties
18. Rights in Technical Data, Computer Software, and Copyright
19. Changes in Performance Period

1) Research Responsibility:

a) The Recipient has full responsibility for the conduct of the research activity supported by this Cooperative Agreement, in accordance with the Recipient's proposal, and the terms and conditions specified in this Cooperative Agreement. Recipients are encouraged to suggest or propose to discontinue or modify unpromising lines of investigation or to explore interesting leads which may appear during the development of the research. However, they must consult the Agreement Officer's Representative (AOR) through the Agreement Officer (AO) before significantly deviating from the objectives or overall program of the research originally proposed.

b) The Recipient shall immediately notify the Agreement Officer of developments that have a significant impact on the award-supported activities. Also, notification shall be given in the case of problems, delays, or adverse conditions which materially impair the ability to meet the objectives of the award. This notification shall include a statement of the action taken or contemplated, and any assistance needed to resolve the situation.

2) **Amendment of Cooperative Agreement:** The only method by which this Cooperative Agreement can be amended is by a formal, written amendment signed by the Agreements Officer. No other communications, whether oral or in writing, shall modify this Cooperative Agreement.

3) **Payments**:

a) Requests for payment for this effort shall be submitted through the Department of the Treasury's Automated Standard Application Payments System (ASAP). Once the Government has submitted a completed ASAP Participation Request forms to ASAP, Recipient will receive an e-mail with further instructions from ASAP.

The recipient organization can use on-line process to request payments. Payment requests are approved or rejected automatically unless placed on review or based on the amount of available funds in the ASAP account. The available balance for an ASAP account is displayed when initiating the payment request. Recipient organizations will receive immediate notification of approval or rejection for all on-line payment requests with the exception of those subject to review. The timing and amount of cash advances shall be as close as is administratively feasible to the Recipient's actual disbursements for direct program costs and the proportionate share of any allowable indirect costs.

b) The Recipient may be paid in advance, provided they comply with the requirements of 2CFR 200.305(b)(1).

c) Reimbursement is the preferred method when the requirements for advance payment cannot be met.

d) Liquidation. The Recipient shall liquidate all obligations incurred under the Cooperative Agreement no later than 90 days after the date of completion. The Recipient shall promptly refund any balances of unobligated cash that the Government has advanced or paid and that is not authorized to be retained by the Recipient for use in other projects. The Agreements Officer is authorized to make a settlement for any upward or downward adjustments to the Federal share of costs after closeout reports are received.

4) **Prior Approvals:** In addition to the prior approvals required by the DoD R&D general terms and conditions, prior written approval is required for the following actions:

The subaward, transfer, or contracting out of any work under this award, unless described in the Recipient's proposal and specifically approved and funded in the Cooperative Agreement Schedule. The Recipient's request for approval shall include the following supporting data:

(i) Basis for contractor selection;
(ii) Justification for lack of competition when competitive bids or offers are not obtained;
(iii) Basis for award cost or price, to include price or cost analysis performed by the Recipient; and
(iv) Approval of the AOR.

5) **Reports**: Reports shall be furnished as specified in the Cooperative Agreement. Report types & descriptions include:

a) Report Types

1) *Quarterly R&D Status Report* - This report is due within 30 calendar days of the end of the previous quarter and shall keep the Government informed of Recipient activity and progress toward accomplishment of Cooperative Agreement objectives and advancement in state-of-the-art on the research and development involved.

2) *Phase Completion Report* - This report is due within 30 calendar days of the end of each phase describing the progress made on the specific milestones as laid out in the SOW.

3) *Monthly Financial Management Report* - This report is due as specified in the Cooperative Agreement and shall be monthly expenditure report that documents cumulative spending and provides a schedule of tasks and events for each report period, with financial expenditures broken down by task.

4) *Annual Technical Report* - This report is due as specified in the Cooperative Agreement, shall document the results of the complete effort. It shall contain brief information on each of the following:

1. A comparison of actual accomplishments with the goals and objectives established for the Cooperative Agreement, the findings of the investigator, or both.
2. Reasons why established goals were not met, if appropriate.
3. Other pertinent information

5) *Special Technical Report* - This report, due as required, shall document the results of a significant task, test, event or symposium.

6) *Final Technical Report* - This report, due 90 days after expiration or termination of the Cooperative Agreement, shall document the results of the complete effort. It shall contain brief information on each of the following:

a) A comparison of actual accomplishments with the goals and objectives established for the Cooperative Agreement, the findings of the investigator, or both.

b) Reasons why established goals were not met, if appropriate.

c) Other pertinent information.

7) *Financial Status Repor*t- shall be submitted on a Standard Form 425 "Federal Financial Report (FFR)" as follows.

a) Interim Status Report – This report is due within 90 days of the end of the interim reporting period (annually). The report shall be on a cash or accrual basis, depending on how the Recipient's accounting records are normally kept.

b) Final Financial Status Report - This report is due 90 days after completion of the Cooperative Agreement. The report shall be on a cash or accrual basis, depending on how the Recipient's accounting records are normally kept.

8) *Report of Federal Cash Transactions [applicable only to advance payment Cooperative Agreements]* – This report, due 15 days following the end of each quarter, shall be submitted on a Standard Form 425. The Recipient shall provide forecasts of Federal cash requirements in the "Remarks" section of the report.

6) Public Release or Dissemination of Information:

a) At this time, DARPA expects the work performed under this Cooperative Agreement to be fundamental research, and it is, therefore, not subject to publication restrictions. Papers resulting from unclassified contracted fundamental research are exempt from prepublication controls and requirements, pursuant to DoD Instruction 5230.27 dated October 6, 1987.

b) All papers resulting from this Cooperative Agreement will include the following

distribution statement: "Approved for public release; distribution is unlimited."

c) Should the character of the research change during Cooperative Agreement performance so that the research is no longer considered fundamental, the Cooperative Agreement will be modified to impose the restrictions on public release and dissemination of information that apply to those research efforts that are not considered fundamental research.

7) Acknowledgment of Sponsorship:

a) The Recipient agrees that in the release of information relating to this Cooperative Agreement, such release shall include a statement to the effect that (1) the project or effort depicted was or is sponsored by the Defense Advanced Research Projects Agency, (2) the content of the information does not necessarily reflect the position or the policy of the Government, and (3) no official endorsement should be inferred.

b) For the purpose of this article, information includes news releases, articles, manuscripts, brochures, advertisements, still and motion pictures, speeches, trade association proceedings, symposia, etc.

c) Nothing in the foregoing shall affect compliance with the requirements of the clause entitled "Security."

8) Intellectual Property Matters: Questions regarding intellectual property matters should be referred to the Agreements Officer (AO). All patent reports (interim and final) shall be submitted using the i-Edison.gov reporting website (http://s-edison.info.nih.gov/iEdison). In the event the Recipient is unable to submit reports through i-Edison, the Recipient may utilize DD Form 882, Report of Inventions and Subcontracts, for submission of interim and final invention reports. The DD Form 882 and all invention disclosures shall be submitted to the AO for proper disposition no later than 120 days after the end of the period of performance.

9) Activities Abroad: The Recipient shall assure that project activities carried on outside the United States are coordinated as necessary with appropriate Government authorities and that appropriate licenses, permits, or approvals are obtained prior to undertaking proposed activities. The awarding agency does not assume responsibility for Recipient compliance with the laws and regulations of the country in which the activities are to be conducted.

10) Security: The Recipient may not be granted access to classified information under this Cooperative Agreement. If security restrictions should happen to apply to certain aspects of the proposed research, the Recipient will be so informed. In the event that the scientific work under this Cooperative Agreement may need classification, or involve access to or storage of any classified data, the Government shall make its decision on the need to classify, or require such access or storage, within 30 days after receipt of written notice from the Recipient. If the decision is affirmative, the Government shall invoke the clause in reference to the "Termination"

proceedings in the DoD R&D general terms and conditions.

11) Research Involving Recombinant DNA Molecules: Any Recipient performing research involving recombinant DNA molecules and/or organisms and viruses containing recombinant DNA molecules agrees, by acceptance of this award, to comply with the National Institutes of Health "Guidelines for Research Involving Recombinant DNA Molecules," July 5, 1994 (59 FR 34496) as amended, or such later revision of those guidelines as may be published in the Federal Register.

12) Restrictions on Printing: Unless otherwise authorized in writing by the AO, reports, data, or other written material produced using funds provided by this Cooperative Agreement and submitted hereunder shall be reproduced only by duplicating processes and shall not exceed 5,000 single page reports or a total of 25,000 pages of a multiple page report. These restrictions do not preclude the writing, editing, and preparation of manuscript or reproducible copy of related illustrative materials if required as a part of this Cooperative Agreement, or incidental printing such as forms or materials necessary to be used by the Recipient to respond to the terms of the Cooperative Agreement. To satisfy the requirements of the Defense Technical Information Center, at least one copy of each technical report submitted to the Defense Technical Information Center must be black typing or reproduction of black on white paper or suitable for reproduction by photographic techniques. Reprints of published technical articles are not within the scope of this paragraph.

In accordance with Executive Order 12873, dated October 20, 1993, as amended by Executive Order 12995, dated March 25, 1996, the Recipient is encouraged to submit paper documents, such as letters or reports, that are printed/copied double-sided on recycled paper that has at least 30 percent postconsumer material.

13) Prohibition on Awarding to Entities that Require Certain Internal Confidentiality Agreements:

a) The Recipient shall not require employees, contractors, or subrecipients seeking to report fraud, waste, or abuse to sign or comply with internal confidentiality agreements or statements prohibiting or otherwise restricting such employees or contractors from lawfully reporting such waste, fraud, or abuse to a designated investigative or law enforcement representative of a Federal department or agency authorized to receive such information.

b) The Recipient must notify its employees, contractors, or subrecipients that the prohibitions and restrictions of any internal confidentiality agreements inconsistent with paragraph (a) of this award provision are no longer in effect.

c) The prohibition in paragraph (a) of this award provision does not contravene requirements applicable to any form issued by a Federal department or agency governing the nondisclosure of classified information.

d) If the Government determines that the Recipient is not in compliance with this award provision, it:

1) Will prohibit the Recipient's use of any funds under this award, in accordance with Federal appropriations law; and

2) May pursue other remedies available for the Recipient's material failure to comply with award terms and conditions.

14) Acceptance and Amendment of Cooperative Agreement:

1) The only method by which this Cooperative Agreement can be amended is by a formal, written amendment signed by the Agreements Officer. No other communications, whether oral or in writing, are valid.

2) The Recipient is not required to countersign the Cooperative Agreement document; however, the Recipient agrees to the conditions specified in the Research Cooperative Agreement Schedule and the Articles herein unless notice of disagreement is furnished to the Agreements Officer within 15 calendar days after the date of the Agreements Officer's signature.

In case of disagreement, the Recipient shall not assess the Cooperative Agreement of any costs of the research unless and until such disagreement(s) is/are resolved.

15) Live Organisms – Human and Animal Subjects:

a) Human Subjects. Cooperative Agreement funds may NOT be used for research that uses uninformed or nonvoluntary humans as experimental subjects. The Recipient is responsible for the protection of the rights and welfare of any human subjects involved in research, development, and related activities supported by this Cooperative Agreement. The Recipient agrees to comply with the Common Federal Policy for the Protection of Human Subjects, codified by the Department of Health and Human Services at 45 CFR part 46 implemented by the Department of Defense at 32 CFR part 219.

Department of the Interior/Interior Business Center (DOI/IBC) collaborates with the Institutional Review Board (IRB) and the U. S. Army Medical Research and Materiel Command (USAMRMC) for DARPA's Second-Level review. No work can be performed on human subjects without a Second-Level review and approval.

b) Animal Welfare. The Recipient shall register its research, development, test, and evaluation or training facility with the Secretary of Agriculture in accordance with 7 U.S.C. 2136 and 9 CFR subpart C, and section 2.30, unless otherwise exempt from this requirement by meeting the conditions in 7 U.S.C. 2136 and 9 CFR parts 1 through 4 for the duration of the activity. The Contractor shall have its proposed animal use approved in accordance with Department of Defense Instruction (DoDI) 3216.01, Use of Animals in DoD Programs, by a DoD Component Headquarters Oversight Office. The Contractor shall furnish evidence of such registration and approval to the Contracting Officer before beginning work under this agreement."

DOI/IBC collaborates with Institutional Animal Care and Use Committee (IACUC) for DARPA's Second-Level review. No work can be performed on animal subjects without a Second-Level review and approval.

The Recipient shall make its animals, and all premises, facilities, vehicles, equipment, and records that support animal care available during business hours and at other times mutually agreeable to the Contractor and the United States Department of Agriculture Office of Animal and Plant Health Inspection Service (USDA/APHIS) representative, personnel representing the DoD component oversight offices, as well as the Contracting Officer, to ascertain that the Contractor is compliant with 7 U.S.C. 2131-2159 and 9 CFR parts 1 through 4.

(1) The Recipient shall acquire animals in accordance with DoDI 3216.01, current at time of award (http://www.dtic.mil/whs/directives/corres/pdf/321601p.pdf).

(2) The Recipient agrees that the care and use of animals will conform with the pertinent laws of the United States, regulations of the Department of Agriculture, and policies and procedures of the Department of Defense (see 7 U.S.C. 2131 et seq., and 9 CFR subchapter A, parts 1 through 4, DoDI 3216.01, Army Regulation 40-33/ SECNAVINST 3900.38C/AFMAN 40-401(I)/DARPAINST 18/USUHSINST 3203). The Contractor shall also comply with DoDI 1322.24, Medical Readiness Training, if this contract includes acquisition of training.

(3) The Agreements Officer may immediately suspend, in whole or in part, work and further payments under this contract for failure to comply with the requirements of paragraphs (a) through (c) of this clause.

(1) The suspension will stay in effect until the Recipient complies with the requirements.

(2) Failure to complete corrective action within the time specified by the Contracting Officer may result in termination of this contract and, if applicable, removal of the Contractor's name from the approved vendor list for live animals used in medical training.

The recipient may request registration of its facility by contacting USDA/APHIS/AC, 4700 River Road, Unit 84, Riverdale, MD 20737-1234, or via the APHIS Animal Care website at: http://www.aphis.usda.gov/wps/portal/aphis/ourfocus/animalwelfare.

The Recipient shall include the substance of this clause, including this paragraph in all subcontracts involving research, development, test, and evaluation or training that use live vertebrate animals.

c) In the event a revised technical proposal with human or animal subject research is incorporated under this Cooperative Agreement, Recipient shall obtain all reviews and approvals prior to beginning any testing on humans or animals.

d) This article shall be flowed down to subcontractors, suitably modified to ensure that the recipient fully complies with this article.

16) Funding Increments and/or Options: The Recipient is advised that the Government's obligation to provide funding for funding increments and/or options included in the Cooperative Agreement is contingent upon (i) satisfactory performance and (ii) the availability of funds. Accordingly, no legal liability on the part of the Government exists unless or until (i) funds are made available to the Government and notice of such availability is confirmed in writing to the Recipient and (ii) performance of the research is deemed satisfactory in the judgment of the Agreements Officer.

17) Delegation of Administrative Duties: The administrative duties listed below have been delegated to the Office of Naval Research (ONR) identified in Item 7 of the Cooperative Agreement Schedule:

a) During performance:

1) Perform government furnished property administration.

2) Receive interim technical, cost/financial and patent reports from Recipient.

3) Review and adjudicate audit findings after receipt of the audit report and ensure that the recipient takes appropriate and timely corrective action, if required.

b) Upon expiration of agreement:

1) Receive final technical, cost/financial and patent reports from Recipient.

2) Obtain final government property report. Perform plant clearance, if required.

3) Assist the awarding Agreements Officer in resolving any questioned costs. Order audit from Department of Health and Human Services (DHHS), if applicable.

4) Perform cost sharing adjustments, if applicable.

5) Assure that all refunds due the Government are received.

6) Complete and submit to the awarding Agreements Officer a Completion Statement for this award.

18) Rights in Technical Data, Computer Software, and Copyright:

(a) Technical Data and Computer Software. Rights are as specified in 2CFR 200.315(d).

(b) Copyright. Rights are as specified in 2CFR 200.315(b).

19) Changes in Performance Period:

Recipient may initiate a one-time extension of the period of performance by up to 12 months unless one or more of the conditions outlined in subparagraphs a.-c. below apply. For one-time extensions, the Recipient must notify the Federal awarding agency in writing with the supporting reasons and revised period of performance at least 30 calendar days before the end of the period of performance specified in the award. This one-time extension may not be exercised merely for the purpose of using unobligated balances.

Extensions require explicit prior Federal awarding agency approval when:

a) The terms and conditions of the award prohibit the extension.

b) The extension requires additional Federal funds.

c) The extension involves any change in the approved objectives or scope of the project.

Montana State University - Bozeman
PREEMPT Program – Cooperative Agreement D18AC00031
Quarterly R&D Status Report

Period Covered by the Report: [Date] through [Date]

Date of Report:

Project Title: Preventing emergence and spillover of bat pathogens in high-risk global hotspots
Total Dollar Value: $8,239,511.00
Program Manager: Dr. James Gimlett, DARPA

Submitted by:
[PI Name]
[Institution]
[Address]

Telephone:
Email:

Subcontractors: [Co-PI name(s) and institution(s)]

TABLE OF CONTENTS

General notes:

- **Contact the program manager and team to report any financial or technical issues** (i.e., please do not wait until a report is due to bring up major issues).
- Clearly indicate if funding from another federal agency (e.g., NIH) has been used to support any data presented.
- Clearly indicate if any content is pre-publication sensitive or proprietary.
- Delete all instructional text from this document before submitting your report.
- Support your claims with data, images, and other evidence.
- Please update the header of each report with the respective quarterly period.
- Please use the following naming convention for report filenames: QR – PI institution – period covered (e.g., QR – University of XYZ – 01OCT2018 to 31DEC2018).
- Quarterly reports are due within 30 days of the quarter end date. For example, if the period ends on March 31, the report must be submitted by April 30.
- Monthly progress updates via conference calls will be scheduled with the program manager and his team.

Definitions:

- **Functional block diagram:** describes the functions and interrelationships of a system in a flock-block diagram style so that one can easily and thoroughly understand the system and the relationship of each of the parts to the whole. If the hardware evolves throughout your project, please provide a block diagram for each evolution (example included).
- **Work Breakdown Structure (WBS):** a hierarchical and incremental decomposition of the project into phases, deliverables and work packages. It is a tree structure that shows the subdivision of effort required to achieve an objective (example included).
- **Deliverable:** a measurable and verifiable outcome or object that a project team must create and deliver according to the terms of an agreement. An intangible deliverable is a particular outcome that the team achieves. A tangible deliverable is a concrete or material object created by the team.
- **Milestone:** a milestone describes the status of the project as represented by an event or moment at which one or more project activities are complete. Milestones can represent the completion of key project tasks, conclusions reached, or questions answered that affect project schedule significantly.
- **Major finding:** data with significant impact (positive or negative).
- **Metrics update:** progress (including delays and issues) toward achieving pre-established metrics of success.
- **SETA:** Science, Engineering, and Technical Assistant (internal DARPA term for technical support staff).

1 Progress Summary

1.1 Major Findings

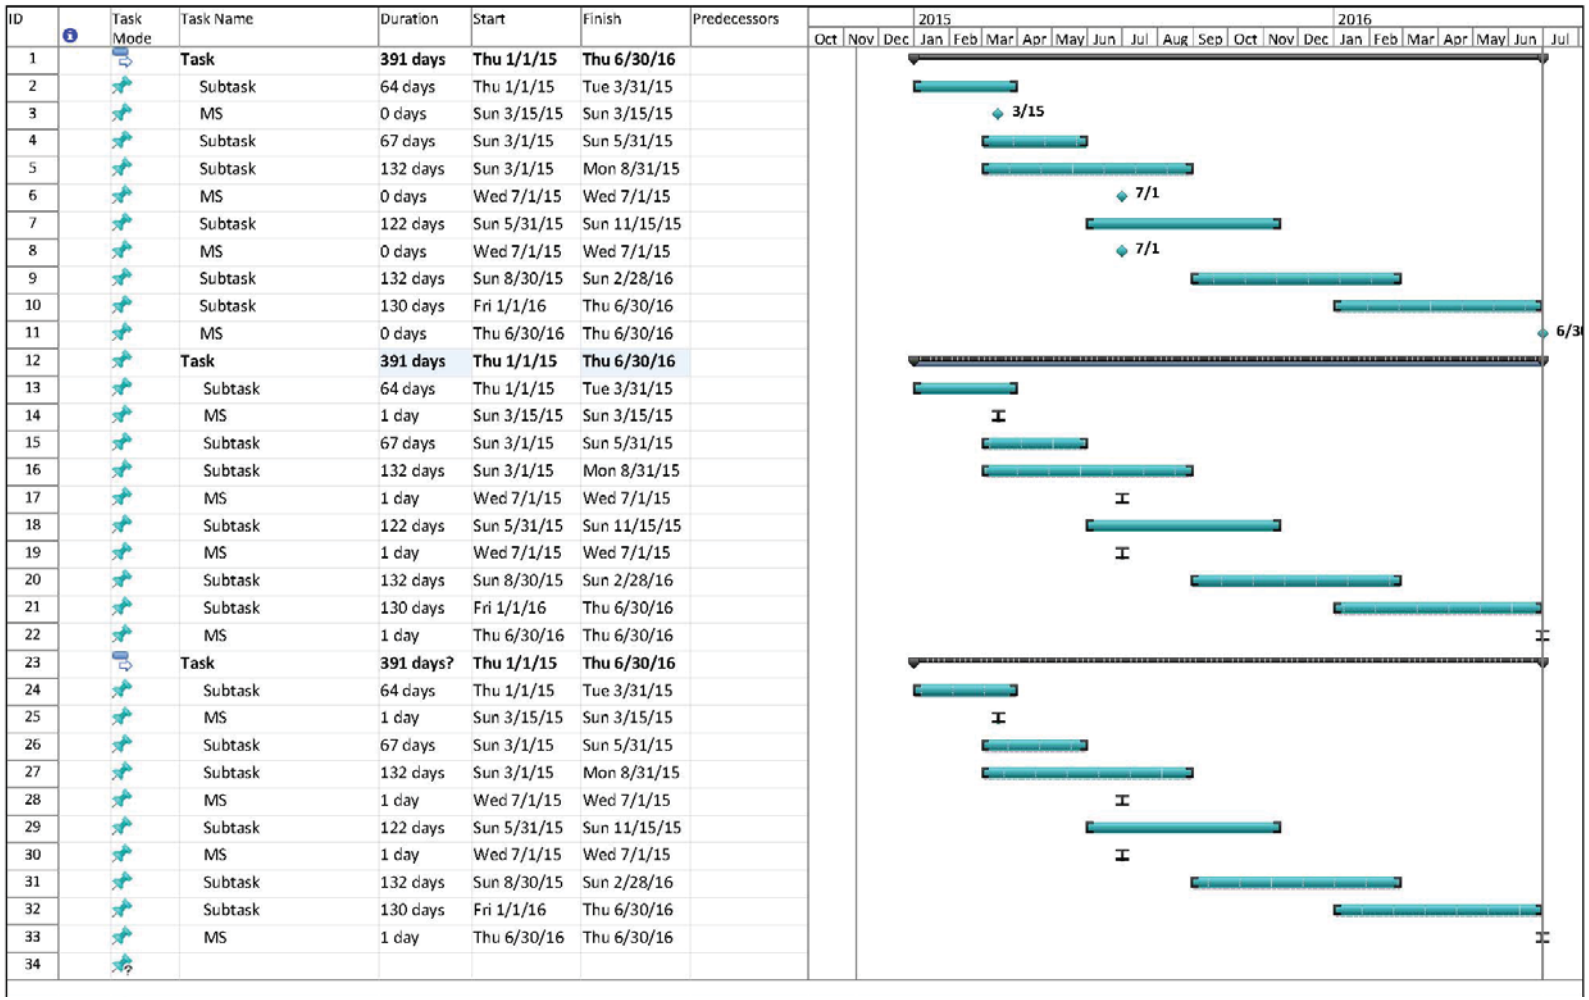
Briefly describe the most significant and salient accomplishment(s) achieved during the ***most recent quarter***. How has this compared to the original project plan?

1.2 Metrics Update

Accomplishment *Include associated task #*	**Month** *Planned vs. achieved*	**Update** *Provide current status, explain any schedule discrepancies, list next steps*

2 Schedule – Milestones and Deliverables

Provide a high-level Gantt chart for Phase I that includes all milestones and deliverables for each task. An example of an acceptable chart is shown below.



ID	Task Mode	Task Name	Duration	Start	Finish	Predecessors
1		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
2		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
3		MS	0 days	Sun 3/15/15	Sun 3/15/15	
4		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
5		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
6		MS	0 days	Wed 7/1/15	Wed 7/1/15	
7		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
8		MS	0 days	Wed 7/1/15	Wed 7/1/15	
9		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
10		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
11		MS	0 days	Thu 6/30/16	Thu 6/30/16	
12		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
13		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
14		MS	1 day	Sun 3/15/15	Sun 3/15/15	
15		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
16		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
17		MS	1 day	Wed 7/1/15	Wed 7/1/15	
18		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
19		MS	1 day	Wed 7/1/15	Wed 7/1/15	
20		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
21		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
22		MS	1 day	Thu 6/30/16	Thu 6/30/16	
23		**Task**	**391 days?**	**Thu 1/1/15**	**Thu 6/30/16**	
24		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
25		MS	1 day	Sun 3/15/15	Sun 3/15/15	
26		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
27		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
28		MS	1 day	Wed 7/1/15	Wed 7/1/15	
29		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
30		MS	1 day	Wed 7/1/15	Wed 7/1/15	
31		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
32		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
33		MS	1 day	Thu 6/30/16	Thu 6/30/16	
34						

Include a corresponding table that provides:

- Short text-identifier for each milestone/deliverable
- Team members associated with each
- Schedule status (provide explanation if behind schedule or significantly ahead of schedule)
- Description of how the milestone/deliverable is contingent or dependent on other parts of the effort (if applicable)

Milestone/ Deliverable	**Team member(s)**	**Due date**	**Date initiated**	**Date completed**	**Status**	**Dependencies** *Across tasks & team members*

3 Task Progress, Accomplishments, and Plans

*Please provide updates from the **most recent quarter**, not a cumulative discussion of the project to date. Support all claims with data. Highlight major accomplishments. Provide explanations and/or justifications for any deviation from the negotiated schedule and spending plan.*

Identify the following for each major task in your SOW; this section will form the bulk of your report:

- Task number (from SOW)
- High-level task description
- Completion status (e.g., ongoing, delayed, etc.)
- Funding associated with the task (spent to date vs. remaining to spend); explain any deviations from your original spend plan

Task #/Title	Brief Description	% Complete	Total $ for task	Spent	Remaining	Explain deviations from planned expenditures

- **Describe planned vs. actual progress towards the goals, milestones, and deliverables of the task; discuss why planned expectations were met, not met, or exceeded; highlight significant accomplishments**
- List next steps
- Support claims with data, images, or other evidence
- Identify and describe all significant challenges and risks encountered during work towards the goals of this task, including:
    - Critical dependencies across tasks and teams
    - Mitigation plan
    - Level of risk (high, medium, or low)
    - Changes in risk status since proposal or last report
    - Anticipated date risk will be resolved

4 Project Coordination, Dissemination, and Translation

4.1 Project Coordination

- Summarize key project planning and coordination over the quarter, including:
  - Meeting date(s), location, purpose
  - Attendees
  - Meeting outcomes, action items

4.2 Dissemination and Translation (if applicable)

- List any new partnerships, collaborators, users, etc.
- Describe potential commercialization pathways/partners

5 Publications and Presentations

Please provide a cumulative update on current and upcoming publications.

Title, Authors	Description/Type	Status
	Presentation to Conference Name	Published
	Paper, Name of Journal	Submitted
	Letter to the Editor, Scientific Organization	In preparation

6 Patents, Invention Disclosures, IDEs, etc…

Please provide a cumulative update of current or upcoming patents, inventions, Investigational Device Exemption (IDE), etc. Examples are listed in the table below.

Title, Authors	Description/Type	Status
	Patent; Name of Patent	Accepted
	FDA IDE	Filed/submitted
	Invention Disclosure	In preparation

Appendix I – Project Context

For future reports, only update this section if any information changes. Please indicate changes using red font.

Teaming and Personnel

Organizational Chart

Insert an organizational chart for your entire team

Contact Information

Please populate the following table with contact information for each team member. Please provide general area of expertise each will provide (e.g., microfluidics). In the last column, list tasks or otherwise briefly describe each individual's involvement in the effort.

Prime Team Members and Contact Information: [Institution]

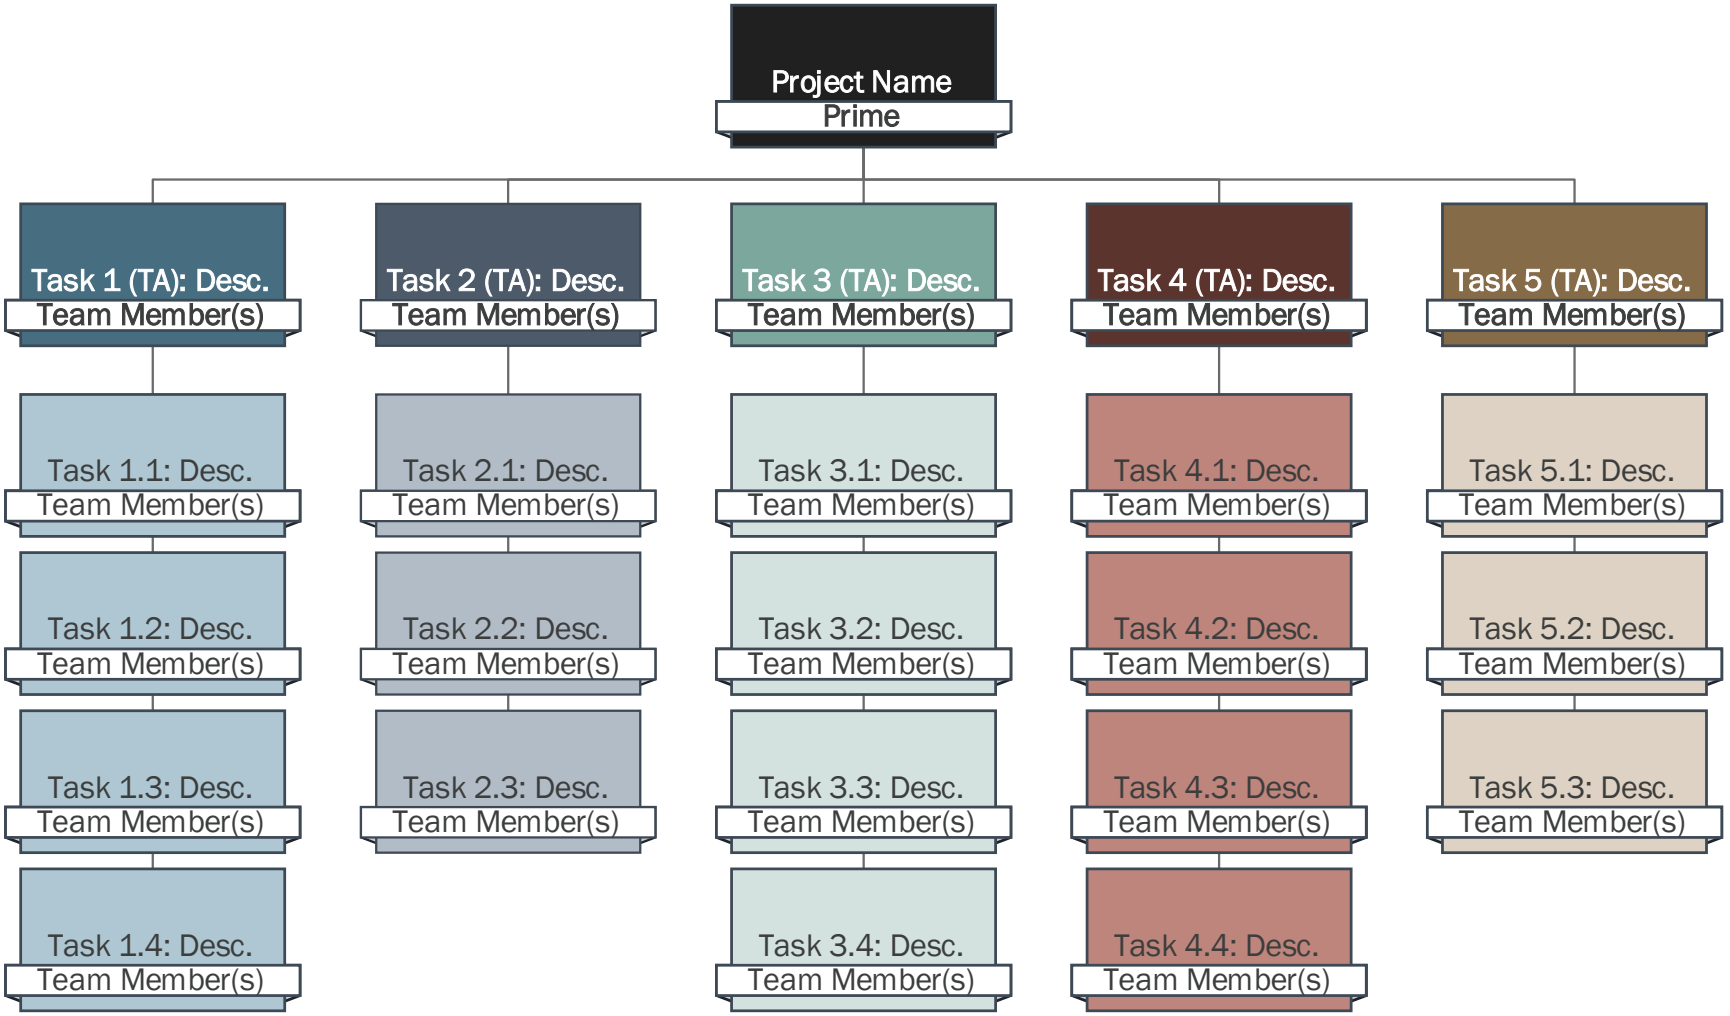
Role	Full name	Phone and email	Areas of Involvement
PI		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Subcontract Team Members and Contact Information: [Institution]

Role	Full name	Phone and email	Areas of Involvement
PI (expertise)		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Work Breakdown Structure

Provide breakdown of tasking and assigned team members as per the template shown below



Monthly Financial Report Template

LINK TO TEMPLATE (click here)

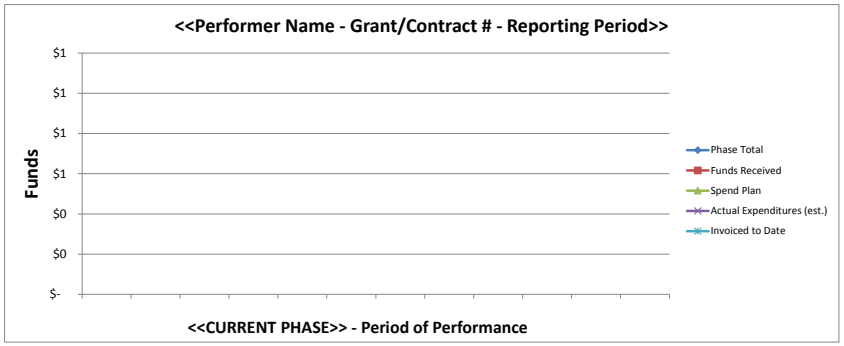
Please use this template to provide monthly financial updates to the PREEMPT team. As you input your data, the graph will automatically update. ***Please keep past reports in this file and create a new tab each month. We want to see all reports in the same file. Title tabs "Phase-Month-Year, " e.g., "Base - January - 2015"***

LINK TO EXAMPLE (click here)

An example of a completed template is also provided. The example graph illustrates a scenario where the performer is under spending. It is designed to show how this template will make it easy for INTERCEPT performers to clearly communicate the status of their effort to DARPA so that both can plan for and initiate contractual actions quickly and effectively.

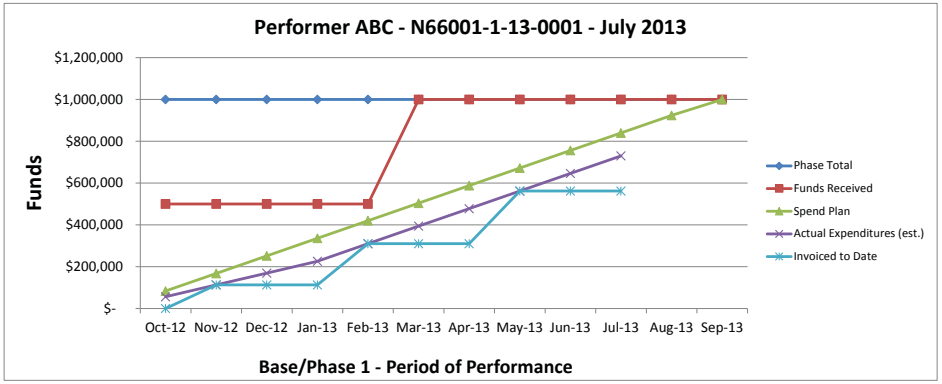
Spend Plan Data	
Period of Performance	The financial report will only cover the current phase (e.g., Base, Option 1, etc.). Use a format similar to "Sep-2013," not "Month 6." In order to plan for continuing resolution requests, DARPA may reach out to you separately to request your projected spend rate for future phases.
Phase Total	Total for current phase *(Example Graph - total is $1,000,000)* .
Funds Received	Funds awarded to date; most efforts are funded incrementally *(Example Graph - this effort received an increment for $500,000 in Oct-2012 to exercise the base, and received the remainder of their base period funding in Mar-2013 (remaining $500,000))* .
Spend Plan	Projected Expenditures must cover the entire phase.
Actual Expenditures (est.)	Actual Expenditures should not be solely based off of invoices you have submitted or received to date. Instead, it should be an accurate (to the extent that is possible) account of the expenses you have actually incurred to date. For example, if a subcontractor has incurred but hasn't invoiced $100,000 worth of work, include the $100,000 in your actual expenditures. Or a large amount of equipment valued at $50,000 that hasn't yet been invoiced should also be factored in to the actual expenditures.
Invoiced to Date	Report the invoices you have submitted to date *(Example Graph - the scenario used in the example graph submits invoices quarterly)* .
Issues/Updates Summary (if applicable)	
Use this section as an opportunity to bring issues, concerns, or updates to the attention of DARPA. For example, you can summarize reasons for over/under-spending, potential no-cost extension requests, invoicing problems, etc.	

***Amounts for Spend Plan, Actual expenditures, Invoiced to Date are cumulative.



Spend Plan Data												
Period of Performance (Current Phase Only)												
Phase Total												
Funds Received												
Spend Plan												
Actual Expenditures (est.)												
Invoiced to Date												

Issues/Updates Summary (if applicable)



Spend Plan Data												
Period of Performance (Current Phase Only)	Oct-12	Nov-12	Dec-12	Jan-13	Feb-13	Mar-13	Apr-13	May-13	Jun-13	Jul-13	Aug-13	Sep-13
Phase Total	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000
Funds Received	$ 500,000	$ 500,000	$ 500,000	$ 500,000	$ 500,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000	$ 1,000,000

Invoiced to Date	$ -	$ 113,000	$ 113,000	$ 113,000	$ 310,100	$ 310,100	$ 310,100	$ 562,100	$ 562,100	$ 562,100		

Issues/Updates Summary (if applicable)

We anticipate that we will need to request a four-month no cost extension (NCE). The NCE is necessary due to delays we experienced while getting Subcontractor #1 under contract. Although our effort's period of performance began in October 2012, the subcontract was finalized and fully-executed in February 2013, which resulted in a four-month delay from the intended start date. Subcontractor #1 is conducting a 12-month study, and cannot speed up their experiments. We would, however, like to begin work on Option 1. We intend to perform these tasks in parallel to the extended Base Period tasks (which are primarily performed by Subcontractor #1).

Preventing emergence and spillover of bat viruses in high-risk global hotspots

STATEMENT OF WORK

July 17th 2018

Milestones by Task

CIES: Cary Institute of Ecosystem Studies; **CSU**: Colorado State University; **Cornell**: Cornell University; **GU**: Griffith University; **JH**: Johns Hopkins University; **MSU: Montana State University**; **PSU**: Penn State University; **RML**: Rocky Mountain Laboratories; **TTU**: Texas Tech University; **UCB**: University of California, Berkeley; **UCLA**: University of California, Los Angeles; **Cambridge**: University of Cambridge.

Note that Rocky Mountain Laboratories (RML) is funded separately by DARPA via IAA/MIPR to NIAID.

TA1

COLLECT AND ANALYZE FIELD SAMPLES

Task 11.01, Data collection: longitudinal sampling of wild bat populations and a captive population. Cambridge, GU, JH, and UCB, with assistance from MSU and TTU, will sample multiple bat populations longitudinally in multiple locations and ship retrospective bat samples to RML or local laboratory for analyses (11.03).

Task 11.02, Data collection: retrospective analysis of bat samples. Cambridge, GU, JH, and UCB will identify, locate, and ship retrospective bat samples to RML or local laboratory for analyses (11.03).

Task 11.03, Lab: screening, metagenomics to identify virus and quasispecies. RML and Cambridge or local laboratory will screen and sequence samples from bats; create a list of sequences that have spilled over from bats to other species; and select sequences for genotype-phenotype modeling.

Task 11.12, Lab: screening retrospective samples from human/domestic livestock hosts. Cambridge, JH, and UCB will identify, locate, and ship retrospective human/livestock samples to RML or local laboratory for analysis; RML or local laboratory will screen samples and create a list of sequences that have spilled over from bats to other species.

Milestones

Australia (GU will do field collection and RML or local laboratory will do sequencing):

- Establish field sites and train field teams (6mths)
- Sample up to 40 bats in 4 bat colonies monthly for 2 years (12mths, 24mths)
- Respond to spillover events or viral pulses within the study area by sampling adaptively until prevalence decreases (12mths, 24mths)
- PCR on all samples for Hendra virus (30mths)
- Sequence all positive samples available (36mths)
- Analyze 1000 retrospective bat samples for henipaviruses (24mths).

Bangladesh (JH will do field collection and in-country PCR; RML will do sequencing):

- Sample up to 40 bats in 4 colonies monthly for 2 years (24mths)
- Respond to spillover events or viral pulses by sampling adaptively until prevalence decreases (24mths)
- PCR on samples for Nipah virus (30mths)
- Sequence all positive samples available (36mths)
- Analyze retrospective bat samples for henipaviruses (24mths).

Ghana (Cambridge will do field collection and laboratory analyses, with some help from RML):

- Locate retrospective human and animal samples suitable for testing and establish sequencing pipeline (6 months)
- Sample up to 120 bats per quarter in 3 colonies, perform PCR testing on the first batches and send positive sample for sequencing (12 months)
- Update sampling effort in bat colonies for year 2 based on 12 months result, for PCR and sequencing, with up to 500 bats to be caught in year 2 (24mths)
- Sample bats in the captive colony every 3 months (24mths)
- Sequence all positive samples available (36mths)

Madagascar (UCB will do field collection and PCR, and RML or local laboratory will do sequencing):

- Establish field sites and train field teams (12mths)
- Sample up to 30 bats in 3 colonies monthly for 2 years (12 mths, 24mths)
- Respond to viral pulses by sampling adaptively until prevalence decreases (12 mth, 24mths)
- Analyze 700 retrospective bat samples for henipaviruses (12mths)
- PCR on samples from bats at Institut Pasteur de Madagascar (30mths)
- Sequence all positive samples available (36mths)

Historic humans and livestock samples (JH, Cambridge, UCB):

- Identify and ship historic samples to RML or local laboratory (6mths)
- PCR on samples from humans and livestock (12mths)
- Sequencing of all positive samples available (18mths)

IDENTIFY HOST IMMUNE SIGNATURES

Task 11.04 Lab: identify host immune and stress signatures in wild bats and in a captive feeding trial. MSU, with help from CSU will measure bat immune signatures. TTU will measure bat stress signatures and nutritional status. A captive feeding trial will be conducted in Ghana (Cambridge), or alternatively, if a natural nutritional stress event occurs in Australia during Phase I, this trial will be conducted in Australia (GU).

Milestones

Immunology on samples from Australia (MSU):

- Validate and optimize tests for each bat species (6mths)
- Immunological markers such as IgG and IgA, biomarkers of cell damage, gene expression of antiviral & proinflammatory proteins, and microbial killing assays for 400 samples (30mths)

Immunology on samples from Ghana (Cambridge):

- Titrate antibodies against Henipaviruses in sera from all PCR-positive bats and a sample of up to 1000 PCR-negative bats, from wild and captive colonies (24 mths).

Stress signatures on samples from Australia (TTU):

- Test up to 720 hair and fecal samples for cortisol (30mths)
- Develop methodology to use bioelectrical impedance analysis to measure body condition of bats (12mths)
- Measure body condition of 400 bats (24mths)

Captive feeding trial (Cambridge, GU)

- Conduct experimental diet manipulation to test the effect of nutritional status on immune state and viral shedding (30mths)

COLLECT ENVIRONMENTAL, ECOLOGICAL, and RESERVOIR HOST DATA

Task 11.10 Remote sensing data, longitudinal short-term weather and long-term climate data, land cover change, human population data, bat movement data. PSU will identify environmental drivers of shedding in Australia and detect large bat colonies through remote sensing. TTU will implement bat telemetry.

Milestones

Remote sensing (PSU):

- Collect data on weather, climate, and land cover change in Australia (24mths)
- Collect data on human population dynamics across space (local/region), time (seasonal/decadal) (24mths)

Bat movement data (TTU):

- Deploy GPS tracking devices on bats in resident and nomadic colonies in Australia (12mths, half deployed; 24mths all deployed)
- Collect, collate, and analyze bat movement data (36mths)

CREATE GENOTYPE-PHENOTYPE MAPS FOR HENIPAVIRUS QUASISPECIES BASED ON *IN VITRO* AND *IN VIVO* WORK

Task 11.13, Lab: in vitro experiments to assess jump potential of quasispecies to new hosts. Cornell and RML will quantify determinants of zoonotic potential for henipavirus strains and quasispecies.

Milestones

Cloning (Cornell; 24 mths):

- Prioritize sequences for 20 F and G pairs to be analyzed for receptor binding and membrane fusion (24mths)
- Synthesize and clone sequences for 20 F and G gene pairs in pCAGGS plasmids (24mths)
- Grow plasmids in bacteria for 20 pairs F and G pairs (24mths)

Receptor binding and membrane fusion assays (Cornell, with help from RML; year 2, 12mths)

- Complete receptor binding assays for 20 G sequences (year 2, 12 months)
- Complete membrane fusion assays in 3 cell lines (human, bat and pig) (year 2, 12 months)

Molecular docking with *in silico* with *in vitro* measurements (RML, with help from Cornell):

- Perform molecular docking analyses (24mths)

Task 11.08, Lab: amplification and transmission dynamics of quasispecies *in vitro* and *in vivo*. RML, with help from CSU, will undertake in vivo experiments to measure phenotypes of henipavirus strains.

Milestones

In vitro and *in vivo* work (RML):

- Use cell culture experiments to analyze growth kinetics of henipaviruses (12mths)
- Develop hamster model for infection experiments (24mths)
- Conduct infection experiments in hamster model to measure infection, shedding, & QS in model hosts (24mths)
- Compare pathogenicity and transmission characteristics in hamster studies with historic studies done by RML (30mths)
- Obtain lung samples at peak virus replication and deep sequence these samples to study QS and selective pressures in a dead-end host (30mths)
- Develop bat models for henipavirus strains with highly pathogenic characteristics in the dead-end host model (36mths)
- Conduct infection experiments and measure infection and shedding in bats (36mths)
- Upon sufficient shedding, conduct contact transmission experiments (36mths)

- Analyze inoculated vs. transmitted virus populations by deep sequencing and identify potential transmissible QS (36mths)
- Analyze QS by established long-read PCR NSG methods (ongoing 42mths)

ANALYZE DATA

Task 11.05, Data analysis: statistical analysis of field data, lab data, environmental and ecological data, and bioinformatics NGS data. Provide statistical support and manage database for project.

Milestones

Data analysis and support (MSU):

- Develop a database structure, system and procedures for providing access to data, and a data visualization platform to facilitate information sharing across tasks and institutions (12mths)
- Clean and check data as it arrives (ongoing over 24mths)
- Graphically visualize and share incoming data for full team (ongoing over 24mths)
- Manage database, analyze data as appropriate, and provide statistical support to the team (ongoing 42mths)

Specific analyses to support other Tasks:

- Use statistical modeling to investigate and quantify links among nutritional status (TTU), stress signatures (TTU), immune status (MSU) and viral shedding (GU/RML/local laboratory) in *wild Australian bats* (30 months)
- Use statistical modeling to investigate and quantify links among nutritional status (Cambridge), stress signatures (MSU), immune status (Cambridge) and viral shedding (Cambridge) *in captive bats* (42 months)

DEVELOP MODELS

Task 11.06, Stochastic models of within- and between-host virus dynamics in bats. Cambridge, with help from GU, will perform stochastic modeling of within and between host virus dynamics in bats.

Milestones

Modeling (Cambridge, GU):

- Develop models of virus transmission within bat populations using prior knowledge from each location (12mths)
- Develop generic models of within-host virus dynamics that incorporate measurable components of the bat immune system (12mths)
- Validate and refine within- and between-host models of virus dynamics in bats using data collected in each field site and laboratory (36mths)

Task 11.15, Mechanistic mathematical modeling of viral fitness within humans, bats, and other host species, iterated with lab studies. UCLA will assemble genotype-to-phenotype maps for reservoir and spillover host species.

Milestones
Viral fitness modeling (UCLA):

- Develop mechanistic model of viral life cycle within cells (12mths)
- Integrate molecular, virologic, cell culture, and animal experiment data (24mths)
- Compare fitness predictions from *in silico* vs *in vitro* data (36mths)
- Integrate models and lab data to establish empirical relations between viral traits and fitness (42mths)

Task 11.09, Phylodynamic models of quasispecies dynamics within bat populations and between host species. MSU, with help from Cambridge and UCLA, will perform phylodynamic modeling of henipaviruses in bat populations.

Milestones
Phylodynamic modeling (MSU, Cambridge, UCLA):

- Formulate model framework to link viral genetics to transmission dynamics (12mths)
- Create models of within- and between-host selection in bat populations (24mths)

Task 12.02, Multi-scale models of zoonotic transmission from bats to humans to predict quasispecies expansions and pulses of excretion. Cambridge, with help from MSU, UCLA and GU, will develop a multi-scale mechanistic modeling framework for pathogen spillover.

Milestones
Multi-scale modeling (Cambridge, MSU, UCLA, GU):

- Develop baseline tools to relate spillover modeling framework from Plowright et al. to field data (12mths)
- Adapt spillover modeling framework from Plowright et al. to henipavirus contexts; identify key challenges to operationalize (18mths)
- Integrate bat virus transmission dynamics, environmental data. and viral fitness models (30mths)
- Develop an integrative model of bat virus spillover that is operationalized to predict probability of spillover at a spatial and temporal scale relevant for intervention (42mths)
- Perform a two-step validation of models:
    - Internal validation of the fitting methods: using simulated data generated by our candidate models, we will infer the parameter values and check the accuracy and precision of the fitting method (ongoing over 42mths)
    - External validation: we will exclude parts of the data iteratively, fit the models to the remaining dataset and check that it predicts correct values for the missing data (ongoing over 42mths)

Task 11.16, Machine learning to ID virus, reservoir traits, zoonotic risk. CIES will perform machine learning analyses to prioritize surveillance by identifying combinations of bat traits and environmental factors that predict spillover.

Milestones

Machine learning analyses (CIES): (all activities below are ongoing over 36mths)

- Collate and pre-process multiple data streams from field teams (environmental data; ecological data on bat populations; data on human ecology)
- Engineer features; impute bat trait data; tune hyperparameters for selected machine learning algorithm; execute cross-validation and target shuffling procedures to diagnose and correct overfitting; produce trait profiles of bat species predicted to be henipavirus positive (first predictions at 6mths).
- Repeat procedures above for models at the ecoregion and country scales (ongoing over 36mths)
- Combine species-level predictions with environmental and human ecological features from the Australian system (i.e., corresponding with viral shedding pulses in local bat populations, satellite imagery on seasonal human population densities, fruiting phenology, climate induced stress). Identify bat species that present the greatest spillover risk to humans, and measurable features that best predict viral shedding (ongoing over 24mths)
- Incorporate data on viral shedding events and conduct machine learning on viral PCR data to identify detectable predictors of viral shedding (Phase 2)
- Assess features corresponding to parameters in a multiscale mechanistic model of viral shedding and provide machine learning support of features to be included in multi-scale models of viral dynamics (e.g., engineering features, estimating parameters impacting viral shedding) (ongoing over 18 months in Phase 2)

TA2

DEMONSTRATE PROOF OF CONCEPT FOR AN ECOLOGICAL INTERVENTION FOR SPILLOVER

Task 22.03, Proof-of-concept for preemption through strategic ecological interventions. GU, with help from TTU and PSU, will do preliminary studies to develop the proof-of-concept demonstration of an ecological intervention to stop spillover. GU, MSU, TTU, Cambridge, CIES, CSU, PSU, RML will all contribute to investigating links between nutritional stress and virus shedding (above).

Milestones.

Demonstrate that bats move from urban roosts to flowering events in native forests (GU, with help from TTU)

- Establish methodology for using movement data to validate bats moving from urban roosts to native forests (6mths)
- Acquire movement data from existing and projected sources (18mths)
- Analyse movement data (24mths).

Demonstrate that bats locate and feed in regenerated habitat

- Develop experimental design and field methods to test use of regenerated forest as feeding habitat by bats (6mths)
- Establish field sites for testing use of regenerated forest as feeding habitat and commence field sampling (12mths)
- Sample up to 30 paired regeneration sites and remnant native habitat (control) sites for feeding bats (18mths)
- Analyse feeding data (24mths)

DEMONSTRATE PROOF OF CONCEPT, FEASIBILITY, AND SCALABILITY OF CHAD/VSV VACCINATION

Task 22.02, Proof-of-concept demonstration of ChAd/VSV vaccination feasibility and scalability of ChAd/VSV vaccination in bats. RML will develop and test a scalable vectored vaccine for target henipaviruses in bats. RML, with help from Cambridge, will assess the feasibility and scalability of the vaccine in bats.

Milestones

Vaccine development (RML):

- Design novel vaccines based on TA1
- Test by comparing measures of protection with historic hamster models (12mths)
- Test the effectiveness of the vaccines against novel henipaviruses (24mths)
- Demonstrate reduced probability of virus transmission among bats and among bats and recipient host species *in vivo* (42mths)
- Quantify scalability of ChAd/VSV vaccination in captive bats in Ghana (42mths)

TRANSITION PLAN

MSU and RML will develop the research transition plan.

Milestones

- Work with the MSU technology transfer infrastructure and personnel, and with the CEPI program to develop partnerships with vaccine manufacturers (30mths)
- Developed an inter-institutional agreement to enable the transfer of our discoveries to industry for commercialization (36mths)

RESEARCH COOPERATIVE AGREEMENT SCHEDULE

1. **Agreement Number**: **D18AC00031** **Amendment 0001**

2. **Recipient Name:** **Montana State University - Bozeman**
307 Montana Hall
Bozeman, MT 59717

3. **Identification Numbers**:

Tax Identification Number (TIN)**: 81-6010045**

Data Universal Numbering System (DUNS) Number**: 625447982**

Commercial and Government Entity (CAGE) Code**: 1KQE9**

Federal Interagency Code for Education (FICE)**: 002532**

Catalog of Federal Domestic Assistance (CFDA): **12.910 – Research and Technology Development**

ASAP Recipient Number: **3034514**

4. **Principal Investigator/Key Personnel**: Dr. Raina Plowright
111A Lewis Hall
P.O. Box 173520
Bozeman, MT 59717-3520

Telephone:
E-mail address:

5. The purpose of this amendment is as follows:

a. Correct the ADPM to Phillip Lamp at Points of Contact 6. e.
b. Update the Quarterly R&D Status and the Monthly Financial Management Report due dates at 14. Reporting Requirements.

6. **Item 6 - Points of Contact is hereby updated as follows:**

6. Points of Contact:

a. Agreements Officer: Department of the Interior
Interior Business Center

Acquisition Services Directorate, Division III
354 South Highway 92
Sierra Vista, AZ 85635

Attention: Doreen Vieira-Cross
Telephone:
FAX:
Email:

b. Cooperative Agreement Administrator:

Department of the Interior
Interior Business Center
Acquisition Services Directorate, Division III
354 South Highway 92
Sierra Vista, AZ 85635

Attention: Deborah Branham
Telephone:
FAX:
Email:

c. Agreements Officer's Representative:

Attention: Dr. James L. Gimlett
Telephone:
Email:

e. DARPA BTO Assistant Director, Program Management (ADPM)

Attention: Phillip Lamp
Email:

7. Item 14 – Reporting Requirements is hereby updated as follows:

14. Reporting Requirements: A final DD Form 882 is required to be filed listing all subject inventions or stating that there were none. In accordance with DARPA-BAA-HR001118S0017, the frequency of the reporting requirement differs from those commonly found in financial assistance agreements due to significant Government involvement throughout the duration of the research cycle. The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 45 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 45 days of the end of each month	See Exhibit A Attachment 2
Special Technical Report	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2019 29 Dec 2020	AOR, AO, PM, ONR & DARPA Research Services
Final Technical Report	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	28 Jan 2021	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

If Optional Phase II is implemented - The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 45 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 45 days of the end of each month	See Exhibit A Attachment 2
Special Technical Reports	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2021	AOR, AO, PM, ONR, & DARPA Research Services
Final Technical Report	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	29 JUL 2022	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

8. Acceptance of this amendment is pursuant to Article 14 Acceptance and Amendment of Cooperative Agreement Exhibit A.

9. All other terms and conditions remain unchanged.

THIS ACTION IS MADE ON BEHALF OF A DoD CUSTOMER UTILIZING DoD FUNDS.

Records: As required by Uniform Guidance, 2 CFR 200, or 45 CFR Part 75, SUBRECIPIENT will maintain appropriate and complete accounts, records, documents and other evidence showing and supporting all costs incurred under this agreement. Subrecipient must retain all records that are required by the terms of the prime award or may reasonably be considered pertinent to the prime award. PTE may verify all expenditure receipts and disburse funds in an amount equal to the approved expenditures. SUBRECIPIENT will allow access to PTE, the Montana Legislative Auditor and/or the Montana Legislative Fiscal Analyst, or other designated persons to all records as may be necessary for audit purposes and to determine compliance with this agreement.

Fly America Act: The Fly America Act requires that all travelers and others performing U.S. Government-financed air travel use U.S. flag carriers to the extent such carriers are available, even if their use would cost more. Even when the entire trip cannot be made on U.S. flag carriers to the extent possible they should be used to the farthest interchange point on a usually traveled route. 301-3.6 (b)(4)(ii). Chartered flights are also subject to the requirements. Cost of duties, visas and value added tax are unallowable. Receipts of travel expenses are required to be submitted for payment.

Liability Exposure: The parties understand and agree that the liability of the State of Montana, PTE, its officials and employees is controlled and limited by the provisions of Title 02, Chapter 09, Montana Code Annotated entitled, *Government Structure and Administration – Liability Exposure and Insurance Coverage*, and the provisions of Title 18, Chapter 01, Part 4 entitled, *Contract Actions Against the State*. Any provision of this agreement, whether or not incorporated herein by reference or otherwise, will be controlled, limited and otherwise modified to limit any liability of the State of Montana, PTE, its officials and employees to that set forth in the above cited laws.

Non-Discrimination: SUBRECIPIENT agrees that no part of this subaward will be performed in a manner which illegally discriminates against any person on the basis of race, color, religion, creed, political ideas, national origin, sex, age, marital status, physical and/or mental handicap.

Assignment Transfer and Subcontracting: There will be no assignment, transfer, or subcontracting of this agreement, or of any interest in this agreement, unless both parties agree in writing. No services required under this agreement may be performed by individuals not subject to this agreement unless both parties agree in writing.

Use of Names: Neither party will include the name of the other party or any of its employees in any advertising, sales promotion or other publicity matter without the prior written consent of the other party.

Reporting Requirements: SUBRECIPIENT will provide to PTE any requested reports necessary to the completion of the prime award, and as detailed in **Attachment 4A.**

Attachment 4A
Subaward Agreement Additional Reporting Requirements

Quarterly R& D Status Reports will be submitted within thirty (30) days after the end of each project quarter (3/31, 6/30, 9/30, and 12/31) to the Pass-through Entity's Principal Investigator identified in Attachment 3. See Exhibit A Attachment 1 for format and instructions.

Monthly Financial Management Report reports will be submitted to the Pass-through Entity's Principal Investigator identified in Attachment 3, within thirty (30) days of the end of the month. See Exhibit A Attachment 2 for format, instructions and example.

Special Technical Reports as requested by DARPA/DOI, due as required, will be submitted when requested by the Pass-through Entity's Principal Investigator identified in Attachment 3.

Final Invention Report (DD Form 882) will be submitted to the Pass-through Entity's Principal Investigator identified in Attachment 3 by 12/20/2020. See Exhibit A Attachment 3 for format and instructions.

TABLE OF CONTENTS

General notes:

- **Contact the program manager and team to report any financial or technical issues** (i.e., please do not wait until a report is due to bring up major issues).
- Clearly indicate if funding from another federal agency (e.g., NIH) has been used to support any data presented.
- Clearly indicate if any content is pre-publication sensitive or proprietary.
- Delete all instructional text from this document before submitting your report.
- Support your claims with data, images, and other evidence.
- Please update the header of each report with the respective quarterly period.
- Please use the following naming convention for report filenames: QR – PI institution – period covered (e.g., QR – University of XYZ – 01OCT2018 to 31DEC2018).
- Quarterly reports are due within 30 days of the quarter end date. For example, if the period ends on March 31, the report must be submitted by April 30.
- Monthly progress updates via conference calls will be scheduled with the program manager and his team.

Definitions:

- **Functional block diagram:** describes the functions and interrelationships of a system in a flock-block diagram style so that one can easily and thoroughly understand the system and the relationship of each of the parts to the whole. If the hardware evolves throughout your project, please provide a block diagram for each evolution (example included).
- **Work Breakdown Structure (WBS):** a hierarchical and incremental decomposition of the project into phases, deliverables and work packages. It is a tree structure that shows the subdivision of effort required to achieve an objective (example included).
- **Deliverable:** a measurable and verifiable outcome or object that a project team must create and deliver according to the terms of an agreement. An intangible deliverable is a particular outcome that the team achieves. A tangible deliverable is a concrete or material object created by the team.
- **Milestone:** a milestone describes the status of the project as represented by an event or moment at which one or more project activities are complete. Milestones can represent the completion of key project tasks, conclusions reached, or questions answered that affect project schedule significantly.
- **Major finding:** data with significant impact (positive or negative).
- **Metrics update:** progress (including delays and issues) toward achieving pre-established metrics of success.
- **SETA:** Science, Engineering, and Technical Assistant (internal DARPA term for technical support staff).

1 Progress Summary

1.1 Major Findings

Briefly describe the most significant and salient accomplishment(s) achieved during the ***most recent quarter***. How has this compared to the original project plan?

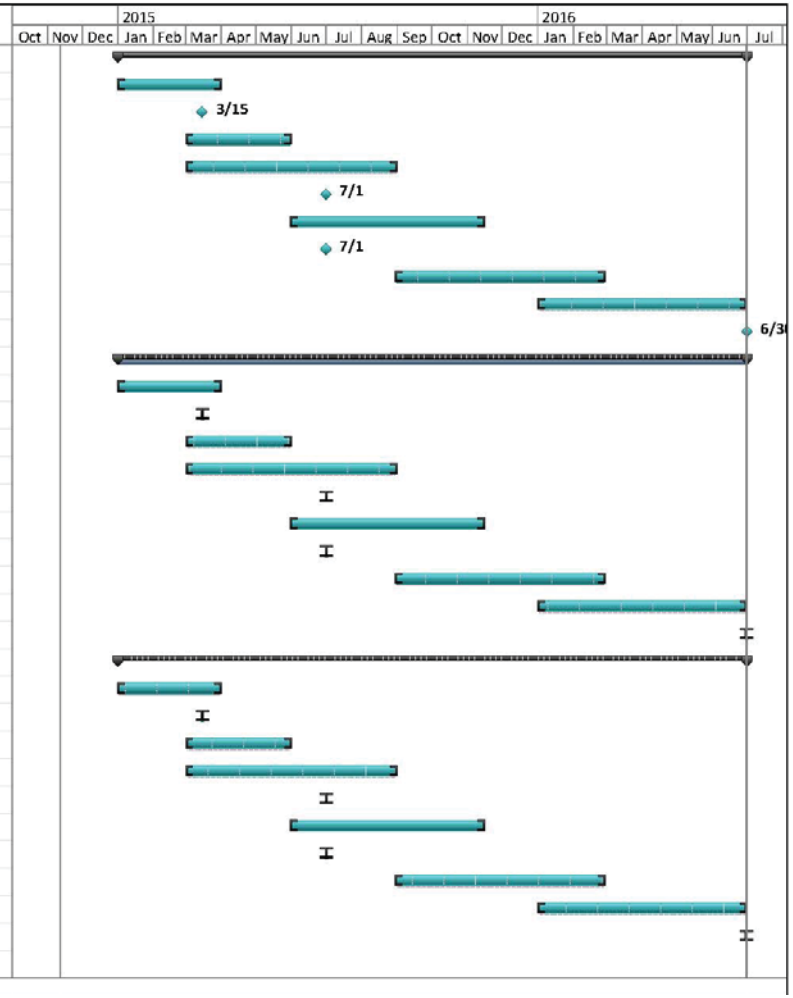
1.2 Metrics Update

Accomplishment *Include associated task #*	**Month** *Planned vs. achieved*	**Update** *Provide current status, explain any schedule discrepancies, list next steps*

2 Schedule – Milestones and Deliverables

Provide a high-level Gantt chart for Phase I that includes all milestones and deliverables for each task. An example of an acceptable chart is shown below.

ID	Task Mode	Task Name	Duration	Start	Finish	Predecessors
1		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
2		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
3		MS	0 days	Sun 3/15/15	Sun 3/15/15	
4		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
5		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
6		MS	0 days	Wed 7/1/15	Wed 7/1/15	
7		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
8		MS	0 days	Wed 7/1/15	Wed 7/1/15	
9		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
10		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
11		MS	0 days	Thu 6/30/16	Thu 6/30/16	
12		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
13		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
14		MS	1 day	Sun 3/15/15	Sun 3/15/15	
15		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
16		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
17		MS	1 day	Wed 7/1/15	Wed 7/1/15	
18		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
19		MS	1 day	Wed 7/1/15	Wed 7/1/15	
20		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
21		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
22		MS	1 day	Thu 6/30/16	Thu 6/30/16	
23		**Task**	**391 days?**	**Thu 1/1/15**	**Thu 6/30/16**	
24		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
25		MS	1 day	Sun 3/15/15	Sun 3/15/15	
26		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
27		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
28		MS	1 day	Wed 7/1/15	Wed 7/1/15	
29		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
30		MS	1 day	Wed 7/1/15	Wed 7/1/15	
31		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
32		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
33		MS	1 day	Thu 6/30/16	Thu 6/30/16	
34						



Include a corresponding table that provides:

- Short text-identifier for each milestone/deliverable
- Team members associated with each
- Schedule status (provide explanation if behind schedule or significantly ahead of schedule)
- Description of how the milestone/deliverable is contingent or dependent on other parts of the effort (if applicable)

Milestone/ Deliverable	**Team member(s)**	**Due date**	**Date initiated**	**Date completed**	**Status**	**Dependencies** *Across tasks & team members*

3 Task Progress, Accomplishments, and Plans

*Please provide updates from the **most recent quarter**, not a cumulative discussion of the project to date. Support all claims with data. Highlight major accomplishments. Provide explanations and/or justifications for any deviation from the negotiated schedule and spending plan.*

Identify the following for each major task in your SOW; this section will form the bulk of your report:

- Task number (from SOW)
- High-level task description
- Completion status (e.g., ongoing, delayed, etc.)
- Funding associated with the task (spent to date vs. remaining to spend); explain any deviations from your original spend plan

Task #/Title	Brief Description	% Complete	Total $ for task	Spent	Remaining	Explain deviations from planned expenditures

- **Describe planned vs. actual progress towards the goals, milestones, and deliverables of the task; discuss why planned expectations were met, not met, or exceeded; highlight significant accomplishments**
- List next steps
- Support claims with data, images, or other evidence
- Identify and describe all significant challenges and risks encountered during work towards the goals of this task, including:
    - Critical dependencies across tasks and teams
    - Mitigation plan
    - Level of risk (high, medium, or low)
    - Changes in risk status since proposal or last report
    - Anticipated date risk will be resolved

4 Project Coordination, Dissemination, and Translation

4.1 Project Coordination

- Summarize key project planning and coordination over the quarter, including:
  - Meeting date(s), location, purpose
  - Attendees
  - Meeting outcomes, action items

4.2 Dissemination and Translation (if applicable)

- List any new partnerships, collaborators, users, etc.
- Describe potential commercialization pathways/partners

5 Publications and Presentations

Please provide a cumulative update on current and upcoming publications.

Title, Authors	Description/Type	Status
	Presentation to Conference Name	Published
	Paper, Name of Journal	Submitted
	Letter to the Editor, Scientific Organization	In preparation

6 Patents, Invention Disclosures, IDEs, etc…

Please provide a cumulative update of current or upcoming patents, inventions, Investigational Device Exemption (IDE), etc. Examples are listed in the table below.

Title, Authors	Description/Type	Status
	Patent; Name of Patent	Accepted
	FDA IDE	Filed/submitted
	Invention Disclosure	In preparation

Appendix I – Project Context

For future reports, only update this section if any information changes. Please indicate changes using red font.

Teaming and Personnel

Organizational Chart

Insert an organizational chart for your entire team

Contact Information

Please populate the following table with contact information for each team member. Please provide general area of expertise each will provide (e.g., microfluidics). In the last column, list tasks or otherwise briefly describe each individual's involvement in the effort.

Prime Team Members and Contact Information: [Institution]

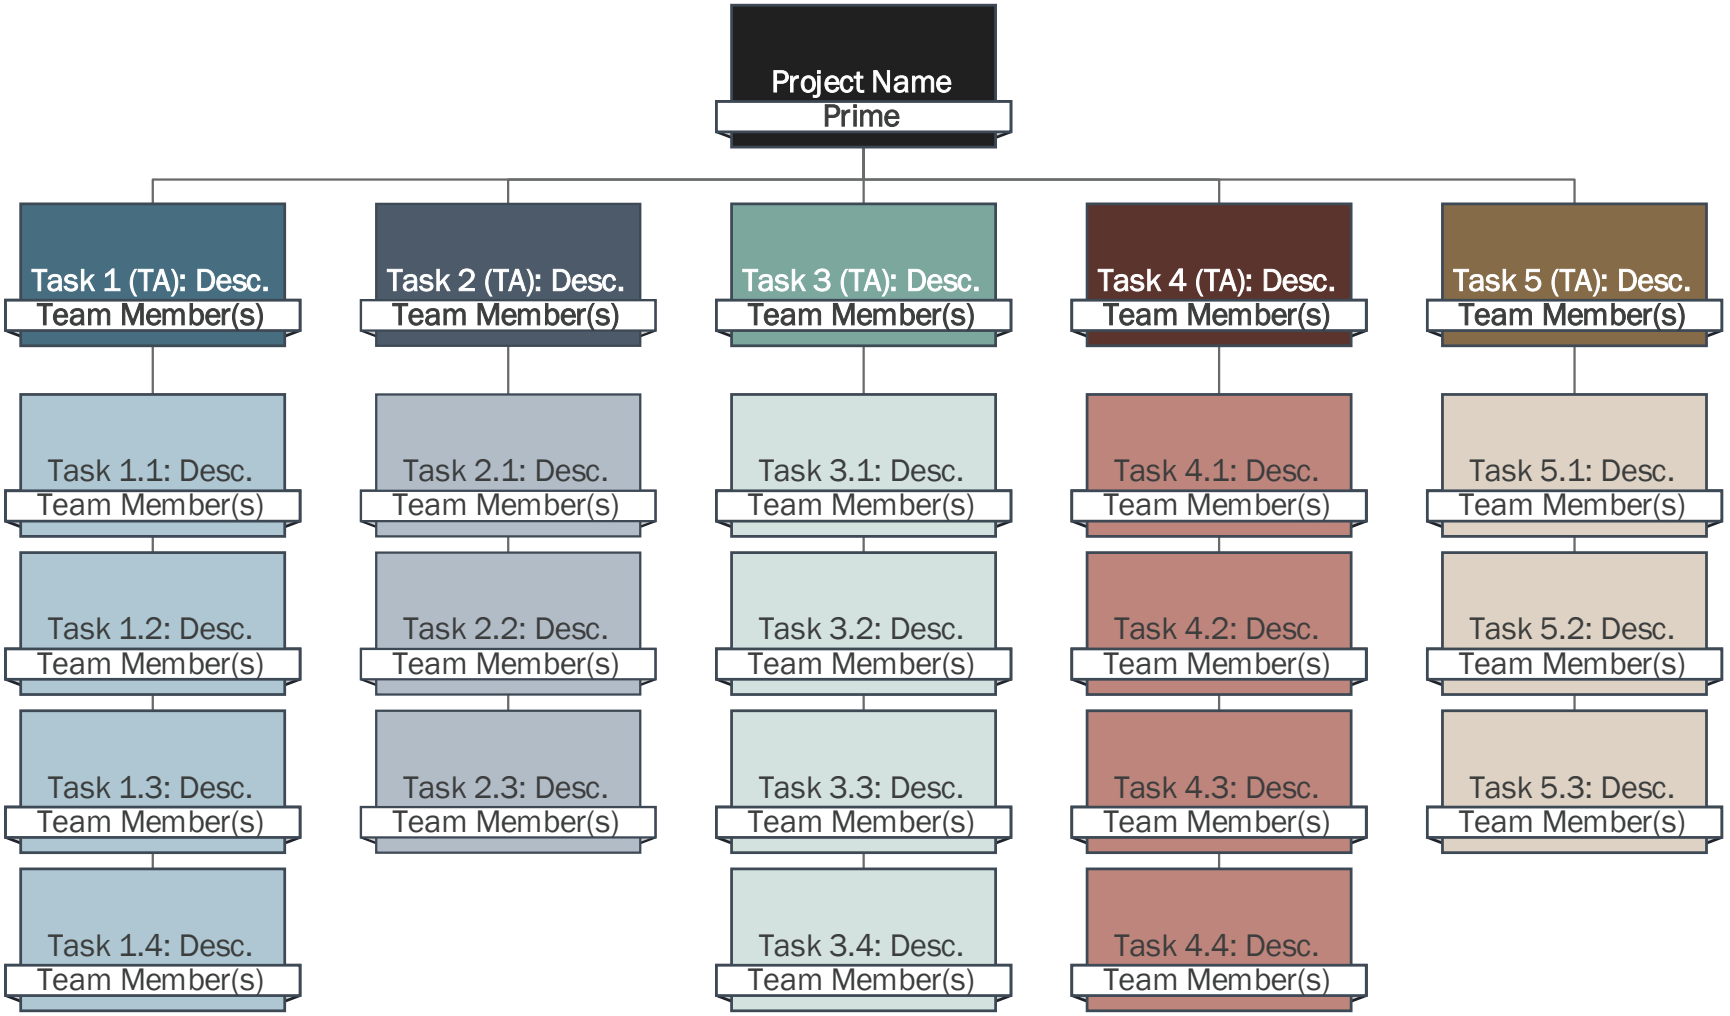
Role	Full name	Phone and email	Areas of Involvement
PI		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Subcontract Team Members and Contact Information: [Institution]

Role	Full name	Phone and email	Areas of Involvement
PI (expertise)		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Work Breakdown Structure

Provide breakdown of tasking and assigned team members as per the template shown below



Monthly Financial Report Template

LINK TO TEMPLATE (click here)

Please use this template to provide monthly financial updates to the PREEMPT team. As you input your data, the graph will automatically update. ***Please keep past reports in this file and create a new tab each month. We want to see all reports in the same file. Title tabs "Phase-Month-Year, " e.g., "Base - January - 2015"***

LINK TO EXAMPLE (click here)

An example of a completed template is also provided. The example graph illustrates a scenario where the performer is under spending. It is designed to show how this template will make it easy for INTERCEPT performers to clearly communicate the status of their effort to DARPA so that both can plan for and initiate contractual actions quickly and effectively.

Spend Plan Data	
Period of Performance	The financial report will only cover the current phase (e.g., Base, Option 1, etc.). Use a format similar to "Sep-2013," not "Month 6." In order to plan for continuing resolution requests, DARPA may reach out to you separately to request your projected spend rate for future phases.
Phase Total	Total for current phase *(Example Graph - total is $1,000,000)* .
Funds Received	Funds awarded to date; most efforts are funded incrementally *(Example Graph - this effort received an increment for $500,000 in Oct-2012 to exercise the base, and received the remainder of their base period funding in Mar-2013 (remaining $500,000))* .
Spend Plan	Projected Expenditures must cover the entire phase.
Actual Expenditures (est.)	Actual Expenditures should not be solely based off of invoices you have submitted or received to date. Instead, it should be an accurate (to the extent that is possible) account of the expenses you have actually incurred to date. For example, if a subcontractor has incurred but hasn't invoiced $100,000 worth of work, include the $100,000 in your actual expenditures. Or a large amount of equipment valued at $50,000 that hasn't yet been invoiced should also be factored in to the actual expenditures.
Invoiced to Date	Report the invoices you have submitted to date *(Example Graph - the scenario used in the example graph submits invoices quarterly)* .
Issues/Updates Summary (if applicable)	
Use this section as an opportunity to bring issues, concerns, or updates to the attention of DARPA. For example, you can summarize reasons for over/under-spending, potential no-cost extension requests, invoicing problems, etc.	

***Amounts for Spend Plan, Actual expenditures, Invoiced to Date are cumulative.

Issues/Updates Summary (if applicable)

We anticipate that we will need to request a four-month no cost extension (NCE). The NCE is necessary due to delays we experienced while getting Subcontractor #1 under contract. Although our effort's period of performance began in October 2012, the subcontract was finalized and fully-executed in February 2013, which resulted in a four-month delay from the intended start date. Subcontractor #1 is conducting a 12-month study, and cannot speed up their experiments. We would, however, like to begin work on Option 1. We intend to perform these tasks in parallel to the extended Base Period tasks (which are primarily performed by Subcontractor #1).

REPORT OF INVENTIONS AND SUBCONTRACTS

(Pursuant to "Patent Rights" Contract Clause) (See Instructions on back)

Form Approved
OMB No. 9000-0095

DD FORM 882 INSTRUCTIONS

GENERAL

This form is for use in submitting INTERIM and FINAL invention reports to the Contracting Officer and for use in reporting the award of subcontracts containing a "Patent Rights" clause. If the form does not afford sufficient space, multiple forms may be used or plain sheets of paper with proper identification of information by item number may be attached.

An INTERIM report is due at least every 12 months from the date of contract award and shall include (a) a listing of "Subject Inventions" during the reporting period, (b) a certification of compliance with required invention identification and disclosure procedures together with a certification of reporting of all "Subject Inventions," and (c) any required information not previously reported on subcontracts containing a "Patent Rights" clause.

A FINAL report is due within 6 months if contractor is a small business firm or domestic nonprofit organization and within 3 months for all others after completion of the contract work and shall include (a) a listing of all "Subject Inventions" required by the contract to be reported, and (b) any required information not previously reported on subcontracts awarded during the course of or under the contract and containing a "Patent Rights" clause.

While the form may be used for simultaneously reporting inventions and subcontracts, it may also be used for reporting, promptly after award, subcontracts containing a "Patent Rights" clause.

Dates shall be entered where indicated in certain items on this form and shall be entered in six or eight digit numbers in the order of year and month (YYYYMM) or year, month and day (YYYYMMDD). Example: April 1999 should be entered as 199904 and April 15, 1999 should be entered as 19990415.

1.a. Self-explanatory.

1.b. Self-explanatory.

1.c. If "same" as Item 2.c., so state.

1.d. Self-explanatory.

2.a. If "same" as Item 1.a., so state.

2.b. Self-explanatory.

2.c. Procurement Instrument Identification (PII) number of contract (DFARS 204.7003).

2.d. through 5.e. Self-explanatory.

5.f. The name and address of the employer of each inventor not employed by the contractor or subcontractor is needed because the Government's rights in a reported invention may not be determined solely by the terms of the "Patent Rights" clause in the contract.

Example 1: If an invention is made by a Government employee assigned to work with a contractor, the Government rights in such an invention will be determined under Executive Order 10096.

Example 2: If an invention is made under a contract by joint inventors and one of the inventors is a Government employee, the Government's rights in such an inventor's interest in the invention will also be determined under Executive Order 10096, except where the contractor is a small business or nonprofit organization, in which case the provisions of 35 U.S.C. 202(e) will apply.

5.g.(1) Self-explanatory.

5.g.(2) Self-explanatory with the exception that the contractor or subcontractor shall indicate, if known at the time of this report, whether applications will be filed under either the Patent Cooperation Treaty (PCT) or the European Patent Convention (EPC). If such is known, the letters PCT or EPC shall be entered after each listed country.

6.a. Self-explanatory.

6.b. Self-explanatory.

6.c. Self-explanatory.

6.d. Patent Rights Clauses are located in FAR 52.227.

6.e. Self-explanatory.

6.f. Self-explanatory.

7. Certification not required by small business firms and domestic nonprofit organizations.

7.a. through 7.d. Self-explanatory.

SUBAWARD EXPENSE BUDGET

COST REIMBURSABLE EXPENSES - NO PAYMENTS IN ADVANCE

Repair and Maint	0.00
Awards	0.00
Participant Support	0.00
Capital Equipment	0.00
Major Renovations	0.00
Facilities and Admin	7,504.00
TOTAL	**21,935.00**

Facilities and Admin (IDC) Basis: MTDC less equip, sub, part supp,awa Rate: 52% Base Amount: 14,431.00

This subaward is being issued to allow work to commence, however, no work with animals shall be authorized until IACUC/ACURO approvals are obtained. Any work with animals that occurs prior to such approval will not be reimbursed by the Pass-Through entity. Subrecipient agrees to provide documentation to Pass-Through entity of all necessary reviews and approvals prior to conducting any animal-related work.

IDENTIFY HOST IMMUNE SIGNATURES

Task 11.04 Lab: identify host immune and stress signatures in wild bats and in a captive feeding trial. CSU will provide advice on how to measure bat immune signatures.

Milestones
Immunology on samples from Australia (MSU):
• Provide advice on tests on bats from Australia (6mths)

Immunology on samples from Ghana (Cambridge):
• Provide advice on tests on bats from Australia (24 mths).

Task 11.08, Lab: amplification and transmission dynamics of quasispecies *in vitro* and *in vivo*. RML, with help from CSU, will undertake in vivo experiments to measure phenotypes of henipavirus strains.

Milestones
• Provide advice on infection experiments (24mths)
• Design experiments and develop IACUC protocols and submit paperwork for ACURO approval (24mths)

DEMONSTRATE PROOF OF CONCEPT, FEASIBILITY, AND SCALABILITY OF CHAD/VSV VACCINATION

Task 22.02, Proof-of-concept demonstration of ChAd/VSV vaccination feasibility and scalability of ChAd/VSV vaccination in bats. RML will develop and test a scalable vectored vaccine for target henipaviruses in bats. RML, with help from Cambridge, will assess the feasibility and scalability of the vaccine in bats.

Milestones
- Provide advice on vaccine development (24mths)

Email or mail invoices to:

Pass-Through Entity Financial Contact

Name	Jennifer Hodges
Address	Montana State University PO Box 173520 Bozeman, MT 59717-3520
Phone	
Email	

Invoices must meet the requirements of the Agreement Terms and Conditions.

1) Reference the MSU Subaward ID **G228-19-W7329** on all invoices.
2) Include current and cumulative costs by budget category (including cost sharing if required) on all invoices.
3) Include period covered by the invoice.
4) Invoices must be signed, dated and certified as to truth and accuracy. Invoices or vouchers requesting payment will include a certification, signed by an authorized official, which reads as follows: "By signing this report, I certify to the best of my knowledge and belief that the report is true, complete, and accurate, and the expenditures, disbursements and cash receipts are for the purposes and objectives set forth in the terms and conditions of the Federal award. I am aware that any false, fictitious, or fraudulent information, or the omission of any material fact, may subject me to criminal, civil or administrative penalties for fraud, false statements, false claims or otherwise. (U.S. Code Title 18, Section 1001 and Title 31, Sections 3729–3730 and 3801–3812)."

Subject: From 140925 CSU subaward with MSU PREEMPT
Attachments: CSU_MSU PreEmpt SubrecipientCommitment Yr 1 less animal work costs.pdf; Schountz UM DARPA Justification Apr 2019.docx

Hi Julie,

This is round umpteenth…. Last week MSU requested budget less the animal costs work. So I sent them the attached word doc highlighting the items that didn't include animal work. They then requested the attached form completed. I did as much as I could. They said once the Animal Work is approved by RML (BSL4 in Montana), MSU will revise award for that the original amount. In the meantime they need this document. Project started 10/1/18. I guess no subs have the subcontract yet.

This is from KR 140925 if you want to check it out. I don't think we what to do a revised budget because they should award the entire amount once the animal work is approved by whomever.

Sure hope it is what they need to get it going.

If you find a phone, it might be easier to discuss.

Susan

Subject: RE: CSU subaward with MSU PREEMPT

Hi Jen,

Budget for non-IACUC/non-ACURO related work includes:
Schountz effort: **$12,935 =** $10,058 (salary) + $2,877 (fringe)
Bozeman, MT project meeting travel: **$1,496**
Direct Total: $14,431
F&A (54%): $7,504
Total: $21,935

I've highlighted the items in the budget justification from October 2018.

Is this sufficient or do you need something else?

Thanks,
Susan

Subject: Re: CSU subaward with MSU PREEMPT

Hi Jennifer,

Thanks very much. I would appreciate get a sub award in place sans animal work. I've cc'd Susan Rogers on this email - she is one of my departmental grant people who has been working on this.

Prior to the change in my scope of work after last October's meeting in Bozeman, I was to provide technical input (effort) and to have travel to the meetings. I paid for the travel to the October meeting with university funds and as far as I'm aware those costs have not been reimbursed. Hopefully, those can be included with this subaward. Susan can provide you with the other details on the non-animal scope of work.

Thanks,

Tony

Type of Organization: Non-US for Profit

Project Information

Address where research will take place ☑ **Same as legal address** **OR:**

Congressional District:

MSU PI: Paina Plowright **Sub PI:** Tony Schountz

Subaward Period of Performance Start: 10/01/18 **End:** 09/30/19

Amount Requested: **Cost Share Amount:**

Prime Sponsor: DARPA

Project Title: Preventing emergence and spillover of bat pathogens in high-risk global hotspots

SECTION A- CERTIFICATIONS

1. Facilities and Administrative Rates- select one:

○ **We have applied our federally negotiated F&A rates. Our negotiated rate agreement is:**

☑ **Available at the URL link**

☐ **Attached**

○ **We do not have a federally negotiated rate and have elected the 10% of Modified Direct Costs de minimis rate.**

○ **We have applied other rates as required by the prime sponsor policies/guidelines.**

2. Compliance- Our Scope of Work includes:

Human Subjects ○ **No** ○ **Yes** **Approval Date:** **OR** ☐ **Pending**

Animal Subjects ○ **No** ○ **Yes** **Approval Date:** **OR** ☐ **Pending**

Subrecipient's IRB and/or IACUC approval must be provided to Montana State University before any subaward work involving Human and/or Animal Subjects may begin. Please forward this document to MSU PI as soon as it is available.

If Human Subjects are involved, have all key personnel completed Human Subjects Training? **Yes** ○ **No** ○ **N/A** ○

3. Conflict of Interest (CoI)- select one:

○ **Not applicable because this project is not being funded by PHS (NIH, HRSA, etc.), or any other sponsor that has adopted the federal financial disclosure requirements (NSF, etc.)**

○ **Subrecipient Organization/Institution certifies that it has an active and enforced conflict of interest policy that is in compliance with the provision of 42 CFR Part 50, Subpart F "Responsibility of Applicants for Promoting Objectivity in Research". Subrecipient also certifies that, to the best of the Institution's knowledge, copies of all disclosures made by Investigators performing research hereunder, which Subrecipient has determined are Financial Conflicts of Interest, are hereby provided to MSU, including disclosure of the management, reduction or elimination of such disclosures, sufficient for MSU to make the required disclosure to the Prime Public Health Service funding agency.**

○ **Subrecipient Organization/Institution certifies that it will comply with MSU's Conflict of Interest Policy located online at: http://www2.montana.edu/policy/conflict_of_interest/ Subrecipient hereby provides to MSU copies of all Investigator disclosures of Significant Financial Interests (as defined in the policy) that are directly related to Subrecipient's work for MSU, including all information necessary for MSU to determine whether such interests are Financial Conflicts of Interest. MSU, in consultation with Subrecipient, shall determine whether the disclosed interest are Financial Conflicts of Interest and, if so, determine how such conflicts shall be managed, reduced, or eliminated and shall report such interests to the funding agency in accordance with the requirements of the Public Health Service regulations, 42 CRF Part 50, Subpart F.**

Montana State University (MSU)- Office of Sponsored Programs
SUBRECIPIENT COMMITMENT FORM

4. Ethics in Research Training (applicable to projects funded by NSF, NIFA or an NIH Training Grant)- select one:

○ **Not applicable because this project is not being funded by NSF, NIFA or an NIH Training Grant.**

◉ **Subrecipient organization/institution hereby certifies that it will ensure that all undergraduates, graduate students, and postdoctoral researchers who will be supported by this proposal will be trained on the oversight in the responsible and ethical conduct of research.**

5. Debarment and Suspension * If checked, attach explanation.

Subrecipient, the PI or any other employee or student participating in this project **are*** ☐ **are not** ☑ debarred, suspended, proposed for debarment, declared ineligible, or otherwise excluded from or ineligible for participation in federal assistance programs, federal contracts or activities.

Subrecipient, the PI or any other employee or student participating in this project **are*** ☐ **are not** ☑ presently indicted for, or otherwise criminally or civilly charged by a government entity.

Subrecipient **has*** ☐ **has not** ☑ within three (3) years preceding this offer, been convicted of or had a civil judgement rendered against them for commission of fraud or criminal offense in connection with obtaining, attempting to obtain, or performing a public (federal, state or local) contract or subcontract; violation of Federal or State antitrust statutes relating to the submission of offers; or commission of embezzlement, theft, forgery, bribery, falsification or destruction of records, making false statements or receiving stolen property.

Subrecipient **has*** ☐ **has not** ☑ within three (3) years preceding this offer, had any contract terminated for default by any Federal Agency.

SECTION B FFATA Information- complete all fields

1. Is Subrecipient owned or controlled by a parent entity? Yes ○ No ○

Note: If yes, please provide DUNS Number and location (City, State, Congressional District, and Country) of parent entity:

2. Is Subrecipient currently registered in System for Award Management, SAM.gov (https://www.sam.gov/portal/public/SAM/)

Yes ◉ No ○ **Note**: SAM.gov Registration is **required** for recipients receiving $25,000 or more from any federally funded project.

3. Executive Compensation- During the previous fiscal year my organization received eighty percent (80%) or more of its annual gross revenues in federal awards AND twenty-five million dollars ($25M) or more in annual gross revenues in federal awards. Yes ○ No ◉

My organization regularly reports information on the compensation of its senior executives in response to section 13(a) or 15(d) of the Securities Exchange Act of 1934 (15 U.S.C. 78m(a), 78 (d) or section 6104 of the Internal Revenue Code of 1986 [26 USC 6104]. Yes ◉ No ○

SECTION C Audit Status- complete all fields

1. Audit Status/ Fiscal Responsibility

○ **Subrecipient organization receives an annual audit in accordance with OMB Uniform Guidance (previously Circular A-133). Were there any findings or exceptions noted?**

No ☑ Yes ☐ If "Yes" attach an explanation.

If your most recent audit is not available on the **Federal Audit Clearinghouse**, you must provide a copy to MSU.

○ **Subrecipient organization is NOT subject to the OMB Uniform Guidance (previously A-133) audit requirements and will complete a mini-audit questionnaire prior to the establishment of a subaward agreement. Subrecipient is not subject to the UG audit requirments because organization:**

☐ Is For-Profit ☐ Is a Foreign Entity ☐ Is a US Government Entity ☐ Expended less than $750,000 (or $500,000 per OMB A-133) in US Federal funds during previous fiscal year

Please note: When applying for funds from agencies under the U.S. Department of Health and Human Services foreign organizations and for-profits that have expended a total of $500,000 or more under one or more awards from the U.S. Department of Health and Human Services (as a direct grantee and/or under a consortium participant) will be required to have a financial-related audit of all HHS awards as defined in, and in accordance with, the Government Auditing Standards or an audit that meets the requirements of OMB Uniform Guidance or Circular A-133 as applicable.

CSU BUDGET JUSTIFICATION

Personnel:

Tony Schountz, PhD, (CSU PI, Years 1-3: 0.69 academic and 0.23 summer months / yr; Year 4: 0.19 academic and 0.06 summer months). Dr. Schountz is an experienced viral immunologist at CSU and maintains the colony of Jamaican fruit bats. He has had the colony for 12 years and has expertise handling bats for inoculations and sample collection, and development of assays to assess host responses during infection. He also has Visiting Scientist status at Rocky Mountain Laboratories where he performs BSL-4 work in collaboration with Dr. Munster. He will also perform PCR array experiments on bat host responses, which generates thousands of data points per experiment for data reduction and analysis. Fringe Rate: 28.6% Salary is calculated each year with ~2.5% inflation. **$10,058 +$2,877 = $12,935**

Miles Eckley, GRA (Yr 1: 0.98 calendar months) – Mr. Eckley will assist with the on stress responses mediated by nutrition and immune modulation and its impact on virus shedding experiments. Fringe Rate: 10.6%.

Travel:

- Travel expenses for PI to travel to RML (Hamilton, MT) for ~2 weeks to perform BSL-4 infection work and sample processing (3 trips at $2,794 per trip); travel to Bozeman, MT for Project Meetings (3 trips at $1,496 per trip). Travel costs: Phase I: $4,290 / year; Phase II: $4,290 (year 3 only).
  - Hamilton, MT (driving with project related items) - $2,794 / trip
    - Lodging:
      - Jackson, WY (half way point): 1 night each way @ $196 / night (w/ tax) = $392
      - Hamilton, MT: 10 nights @ $91/ night (w/ tax) = $910
    - Mileage = 1,600 miles (~800 miles from Fort Collins, CO to Hamilton, MT plus driving in Hamilton during trip) @ $0.49 / mi = $784
    - Per diem Meals = 12 days @ $59 / day = $708
  - Bozeman, MT $1,496 / trip
    - Airfare: $790 (non-stop)
    - Lodging: 2 nights @ $149 / night (w/ tax) = $298
    - Per diem Meals: 3 days @ $59/ day = $177
    - Car Rental: 3 days @ $77/day = $231

Other Direct:

- Bat colony maintenance: Daily bat room colony care and maintenance for project is calculated $26.85 / day. Phase I: $9,800 / yr; Phase II: year 3: $9,800, year 4: $4,900. Stress response experiment per diem charges are calculated at $4.72 / day / cage * 4 cages of 5 bats for 21 days ($396)
- Bat transportation costs: Transporting of non-infected bats to RML estimated at $1,000 / shipment. One shipment is expected each year.
- Tuition: Yr 1: $1,716 - corresponds to effort on project.

F&A: Modifiied Total Direct: 52%.

Subject: Memo to: Colorado State University G228-19-W7329 Agreement signed

Attached please find the fully executed MSU Subaward referenced above**.** We look forward to working with you on this project.

Please remember: This subaward is being issued to allow work to commence, however, no work with animals shall be authorized until IACUC/ACURO approvals are obtained. Any work with animals that occurs prior to such approval will not be reimbursed by the Pass-Through entity. Subrecipient agrees to provide documentation to Pass-Through entity of all necessary reviews and approvals prior to conducting any animal-related work.

All invoices for this project should be submitted according to the procedures specified in Attachment 6, Subaward Agreement Invoicing Procedures.

If you need any further assistance, please feel free to email subawards@montana.edu or call

Sincerely,
Jennifer

PTE Principal Investigator: **Raina Plowright**	Principal Investigator: **Tony Schountz**
PTE Awarding Agency: **Defense Advanced Research Projects Agency**	PTE Awarding Agency ID: D18AC00031
PTE CFDA 12.910 Research and Technology Development	This subaward is subject to OMB Uniform Guidance PTE FAIN: D18AC00031

Subaward Title: Preventing emergence and spillover of bat pathogens in high-risk global hotspots

Subaward Period of Performance	Authorized Amount	**Subaward ID: G228-19-W7329**
Start **10/01/2018** End **09/30/2019**	**21,935.00**	1. Cost Sharing is Not Required 2. This award is a Cost Reimbursable agreement 3. Project Reporting is Required (Attachments 4 and 4A)

Terms and Conditions

1) PTE hereby awards a cost reimbursable subaward, as described above, to SUBRECIPIENT. The Budget and Scope of Work for this subaward are shown in Attachments 5 and 5A. In its performance of subaward work, SUBRECIPIENT shall be an independent entity and not an employee or agent of PTE.
2) PTE shall reimburse SUBRECIPIENT not more often than monthly for allowable costs.
3) All invoices shall be submitted using SUBRECIPIENT's standard invoice, but at a minimum shall include current and cumulative costs (including cost sharing), subaward number, and certification as to truth and accuracy of the invoice as required in 2 CFR 200.415 . Invoices that do not reference PTE's subaward number shall be returned to SUBRECIPIENT. Invoices and questions concerning invoice receipt or payment should be directed to the appropriate party's Financial Contact, as shown in Attachment 3 and detailed in Attachment 6.
4) A final statement of cumulative costs incurred, including cost sharing, marked "FINAL", must be submitted to PTE's Financial Contact NOT LATER THAN forty-five (45) days after subaward end date. The final statement of costs shall constitute SUBRECIPIENT's final financial report.
5) All payments shall be considered provisional and subject to adjustment within the total estimated cost in the event such adjustment is necessary as a result of an adverse audit finding against the SUBRECIPIENT.
6) PTE reserves the right to reject an invoice, in accordance with 2 CFR 200.305.
7) Matters concerning the technical performance of this subaward should be directed to the appropriate party's Principal Investigator, as shown in Attachment 3.
8) Matters concerning the request or negotiation of any changes in the terms, conditions, or amounts cited in this subaward agreement, and any changes requiring prior approval, should be directed to the appropriate party's Administrative Contact, as shown in Attachment 3. Any such changes made to this subaward agreement require the written approval of each party's Authorized Official, as shown in Attachment 3.
9) Substantive changes (for example, change in Scope of Work, Attachment 5A) made to this subaward agreement require the written approval of each party's Authorized Official as shown in Attachment 3. The PTE may issue non-substantive changes to the Period of Performance Bilaterally.
10) Each party shall be responsible for its negligent acts or omissions and the negligent acts or omissions of its employees, officers, or directors, to the extent allowed by law.
11) Either party may terminate this agreement with thirty (30) days written notice to the appropriate party's Administrative Contact, as shown in Attachment 3. PTE shall pay SUBRECIPIENT for termination costs as allowable under Uniform Guidance, 2 CFR 200, or 45 CFR Part 75 Appendix IX, "Principles for Determining Costs Applicable to Research & Development under Grants and Contracts with Hospitals," if applicable. If the PTE Awarding Agency suspends or terminates the prime award in whole or in part, PTE may suspend or terminate this subaward accordingly.
12) No-cost extensions require the approval of the PTE. Any requests for a no-cost extension should be addressed to and received by the Administrative Contact, as shown in Attachment 3, not less than thirty (30) days prior to the desired effective date of the requested change.
13) The subaward is subject to the terms and conditions of the PTE Award and other special terms and conditions, as identified in Attachment 2.
14) By signing below SUBRECIPIENT makes the certifications and assurances shown in Attachments 1 and 2.

By an Authorized Official of Montana State University	By an Authorized Official of SUBRECIPIENT
Dale Huls — 5/30/2019 Signature — Date	Signature — Date Ashley Stahle cn=Ashley Stahle, o=Colorado State University, ou=Sponsored Programs, email=ashley.stahle@colostate.edu, c=US 2019.05.30 15:03:14 -06'00'

OSP Ref W7329-G19-228	

By signing the Subaward Agreement, the authorized official of SUBRECIPIENT certifies, to the best of his/her knowledge and belief, that:

Certification Regarding Lobbying

1) No Federal appropriated funds have been paid or will be paid, by or on behalf of the SUBRECIPIENT, to any person for influencing or attempting to influence an officer or employee of any agency, a Member of Congress, an officer or employee of Congress, or an employee of a Member of Congress in connection with the awarding of any Federal contract, the making of any Federal grant, the making of any Federal loan, the entering into of any cooperative agreement, and the extension, continuation, renewal, amendment, or modification of any Federal contract, grant, loan, or cooperative agreement.

2) If any funds other than Federal appropriated funds have been paid or will be paid to any person for influencing or intending to influence an officer or employee of any agency, a Member of Congress, an officer or employee of Congress, or an employee of a Member of Congress in connection with this Federal contract, grant, loan, or cooperative agreement, the SUBRECIPIENT shall complete and submit Standard Form -LLL, "Disclosure Form to Report Lobbying," to the PASS-THROUGH ENTITY.

3) The SUBRECIPIENT shall require that the language of this certification be included in the award documents for all subawards at all tiers (including subcontracts, subgrants, and contracts under grants, loans, and cooperative agreements) and that all subrecipients shall certify and disclose accordingly.

This certification is a material representation of fact upon which reliance was placed when this transaction was made or entered into. Submission of this certification is a prerequisite for making or entering into this transaction imposed by section 1352, title 31, U. S. Code. Any person who fails to file the required certification shall be subject to a civil penalty of not less than $10,000 and not more than $100,000 for each such failure.

Debarment, Suspension, and Other Responsibility Matters

SUBRECIPIENT certifies by signing this Subaward Agreement that neither it nor its principals are presently debarred, suspended, proposed for debarment, declared ineligible, or voluntarily excluded from participation in this transaction by any federal department or agency.

Audit and Access to Records

Subrecipient certifies by signing this Subaward Agreement that it complies with the Uniform Guidance, will provide notice of the completion of required audits and any adverse findings which impact this subaward as required by parts 200.501- 200.521, and will provide access to records as required by parts 200.336, 200.337, and 200.201 as applicable.

See Copy of Award Notice Attachment 2A.

Special Terms and Conditions:

1. Copyrights
   SUBRECIPIENT grants to PASS-THROUGH ENTITY (PTE) an irrevocable, royalty-free, nontransferable, non-exclusive right and license to use, reproduce, make derivative works, display, and perform publicly any copyrights or copyrighted material (including any computer software and its documentation and/or databases) first developed and delivered under this Agreement solely for the purpose of and only to the extent required to meet PTE's obligations to the Federal Government under its Prime Award.
2. Data Rights
   SUBRECIPIENT grants to PTE the right to use data created in the performance of this Agreement solely for the purpose of and only to the extent required to meet PTE's obligations to the Federal Government under its Prime Award.
3. Carry Forward
   Carry Forward requests must be sent to PTE's Authorized Official contact, as shown in Attachment 3.

Additional Special Terms: See Copy of Award Notice Attachment 2A.

Assign: 01

11. **Terms and Conditions:** This cooperative agreement is subject to General Terms and Conditions for Cooperative Agreements set forth in the attached Exhibit A and to any Special Terms and Conditions contained in Item 17 of this Research Cooperative Agreement Schedule.

12. **Acceptance of Cooperative Agreement:** Acceptance of this cooperative agreement is pursuant to Article 14 of Exhibit A. The Recipient is not required to countersign the Cooperative Agreement document; however, the Recipient agrees to the conditions specified in the Research Cooperative Agreement Schedule and the Articles herein unless notice of disagreement is furnished to the Agreements Officer within 15 calendar days after the date of the Agreements Officer's signature. In case of disagreement, the Recipient shall not assess the Cooperative Agreement of any costs of the research unless and until such disagreement(s) is/are resolved.

13. **Payments:** Payments will be made in accordance with Article 3 of Exhibit A.

14. **Reporting Requirements:** A final DD Form 882 is required to be filed listing all subject inventions or stating that there were none. In accordance with DARPA-BAA-HR001118S0017, the frequency of the reporting requirement differs from those commonly found in financial assistance agreements due to significant Government involvement throughout the duration of the research cycle. The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 30 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 30 days of the end of each month	See Exhibit A Attachment 2
Special Technical Report	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2019 29 Dec 2020	AOR, AO, PM, ONR & DARPA Research Services
Final Technical Report	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	28 Jan 2021	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

If Optional Phase II is implemented - The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 30 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 30 days of the end of each month	See Exhibit A Attachment 2
Special Technical Reports	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2021	AOR, AO, PM, ONR, & DARPA Research Services
Final Technical Report	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	29 JUL 2022	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

15. **Substantial Involvement:** Substantial involvement is expected between the U. S. Government and the Recipient when carrying out the activity contemplated in this Agreement.

    Substantial Government involvement will include:

    a. DARPA review and approval required after completion of one phase of the project to move on to the next phase

b. DARPA monitoring of the work with the potential of redirecting work because of interrelationships with other projects
c. DARPA review and collaboration in the development of research and analyses protocols necessary to complete the work

16. Funding Increments and Options: The Government's obligation to provide funding for increments and/or options is pursuant to Article 16 of Exhibit A.

17. Special Terms and Conditions:

a. Assurance by University to adhere to the Defense Advanced Research Agency's (DARPA) policy and communication on Dual Use of Research Concerns (DURC).

i. Definitions:

1. "Dual use research" is research conducted for legitimate purposes that generates knowledge, information, technologies, and/or products that can be utilized for benevolent or harmful purposes.
2. "Dual use research of concern," or "DURC," is life sciences research that, based on current understanding, can be reasonably anticipated to provide knowledge, information, products, or technologies that could be directly misapplied to pose a significant threat with broad potential consequences to public health and safety, agricultural crops and other plants, animals, the environment, materiel, or national security.

ii. DURC Policy: Any data with potential dual use of research concerns emerging from DARPA funded research shall be evaluated by the team, communicated to DARPA, and submitted for evaluation by team's Institutional Review Entity (IRE). If the IRE and DARPA determine that results or information obtained during the course of funded effort could be considered DURC, the IRE and DARPA will jointly determine an acceptable risk mitigation plan including a responsible publication strategy to determine appropriate venues and content that can and should be released to the public.

iii. Reporting Process: The principal investigator (PI) shall collect information about team's activities (including experiments, data collection, and data processing) on any emergent issues of relevance to DURC and GOF, and send a brief monthly report to DARPA (including negative responses). Within 15 days of a notification of a potential DURC issue the PI shall submit the findings to team's Institutional Review Entity (IRE). If the IRE determines that the findings in question are not of concern, the reported findings are not subject to additional review or oversight, but future activities must continue to be assessed by the PI in monthly reports. If IRE determines the findings could be considered DURC, the PI shall notify DARPA within 10 days of IRE's assessment along with a copy of the assessment.

b. This research **DOES NOT** require the use of Human Subjects.
c. This research **DOES** require the use of Animal Subjects. See Article 15 of Exhibit A. **No animal studies may be conducted using funds from this award until Institutional Animal Care and Use Committee (IACUC) and DARPA second level review approvals are received.**

IACUC Protocol #: Pending Approval — Expiration Date: Pending Approval
Second-level Review #: Pending Approval — Renewal due date: Pending Approval

d. This research **DOES NOT** have restricted data rights.

THIS ACTION IS MADE ON BEHALF OF A DoD CUSTOMER UTILIZING DoD FUNDS.

EXHIBIT A

JULY 2018
DARPA AGENCY SPECIFIC TERMS AND CONDITIONS

This award is subject to the DoD Research and Development (R&D) general terms and conditions, which can be found at https://www.onr navy mil/Contracts-Grants/submit-proposal/grants-proposal/grants-terms-conditions.aspx under the header "DoD Research and Development General Terms and Conditions," dated July, 2018 and are incorporated herein. The DARPA Agency Specific Terms and Conditions supplement the DoD Research and Development general terms and conditions. This document addresses agency-specific concerns in addition to the above referenced regulations. Award recipients (hereafter, recipient) are accountable for all applicable statutory and regulatory requirements that govern these awards, even if not specifically listed in this document or documents referenced herein.

ORDER OF PRECEDENCE

Any inconsistencies in the requirements of this award shall be resolved in the following order:

- Federal statutes
- Federal regulations
- 2 CFR part 200, as modified and supplemented by DoD's interim implementation found in 2 CFR part 1103
- Award-specific terms and conditions (DARPA Agency Specific terms and conditions)
- DoD Research and Development general terms and conditions

In case of disagreement with any requirements of this award, the Recipient shall contact the Agreements Officer listed in the award document in order to resolve the issue. The Recipient shall not assess any costs to the award or accept any payments until the issue is resolved.

1. Research Responsibility
2. Amendment of Cooperative Agreement
3. Payments
4. Prior Approvals
5. Reports
6. Public Release or Dissemination of Information
7. Acknowledgment of Sponsorship
8. Intellectual Property Matters
9. Activities Abroad
10. Security
11. Research Involving Recombinant DNA Molecules
12. Restrictions on Printing
13. Prohibition on Awarding to Entities that Require Certain Internal Confidentiality Agreements
14. Acceptance and Amendment of Cooperative Agreement
15. Live Organisms – Human and Animal Subjects
16. Funding Increments and/or Options
17. Delegation of Administrative Duties
18. Rights in Technical Data, Computer Software, and Copyright
19. Changes in Performance Period

1) Research Responsibility:

a) The Recipient has full responsibility for the conduct of the research activity supported by this Cooperative Agreement, in accordance with the Recipient's proposal, and the terms and conditions specified in this Cooperative Agreement. Recipients are encouraged to suggest or propose to discontinue or modify unpromising lines of investigation or to explore interesting leads which may appear during the development of the research. However, they must consult the Agreement Officer's Representative (AOR) through the Agreement Officer (AO) before significantly deviating from the objectives or overall program of the research originally proposed.

b) The Recipient shall immediately notify the Agreement Officer of developments that have a significant impact on the award-supported activities. Also, notification shall be given in the case of problems, delays, or adverse conditions which materially impair the ability to meet the objectives of the award. This notification shall include a statement of the action taken or contemplated, and any assistance needed to resolve the situation.

2) **Amendment of Cooperative Agreement:** The only method by which this Cooperative Agreement can be amended is by a formal, written amendment signed by the Agreements Officer. No other communications, whether oral or in writing, shall modify this Cooperative Agreement.

3) **Payments**:

a) Requests for payment for this effort shall be submitted through the Department of the Treasury's Automated Standard Application Payments System (ASAP). Once the Government has submitted a completed ASAP Participation Request forms to ASAP, Recipient will receive an e-mail with further instructions from ASAP.

The recipient organization can use on-line process to request payments. Payment requests are approved or rejected automatically unless placed on review or based on the amount of available funds in the ASAP account. The available balance for an ASAP account is displayed when initiating the payment request. Recipient organizations will receive immediate notification of approval or rejection for all on-line payment requests with the exception of those subject to review. The timing and amount of cash advances shall be as close as is administratively feasible to the Recipient's actual disbursements for direct program costs and the proportionate share of any allowable indirect costs.

b) The Recipient may be paid in advance, provided they comply with the requirements of 2CFR 200.305(b)(1).

c) Reimbursement is the preferred method when the requirements for advance payment cannot be met.

d) Liquidation. The Recipient shall liquidate all obligations incurred under the Cooperative Agreement no later than 90 days after the date of completion. The Recipient shall promptly refund any balances of unobligated cash that the Government has advanced or paid and that is not authorized to be retained by the Recipient for use in other projects. The Agreements Officer is authorized to make a settlement for any upward or downward adjustments to the Federal share of costs after closeout reports are received.

4) **Prior Approvals:** In addition to the prior approvals required by the DoD R&D general terms and conditions, prior written approval is required for the following actions:

The subaward, transfer, or contracting out of any work under this award, unless described in the Recipient's proposal and specifically approved and funded in the Cooperative Agreement Schedule. The Recipient's request for approval shall include the following supporting data:

(i) Basis for contractor selection;
(ii) Justification for lack of competition when competitive bids or offers are not obtained;
(iii) Basis for award cost or price, to include price or cost analysis performed by the Recipient; and
(iv) Approval of the AOR.

5) **Reports**: Reports shall be furnished as specified in the Cooperative Agreement. Report types & descriptions include:

a) Report Types

1) *Quarterly R&D Status Report* - This report is due within 30 calendar days of the end of the previous quarter and shall keep the Government informed of Recipient activity and progress toward accomplishment of Cooperative Agreement objectives and advancement in state-of-the-art on the research and development involved.

2) *Phase Completion Report* - This report is due within 30 calendar days of the end of each phase describing the progress made on the specific milestones as laid out in the SOW.

3) *Monthly Financial Management Report* - This report is due as specified in the Cooperative Agreement and shall be monthly expenditure report that documents cumulative spending and provides a schedule of tasks and events for each report period, with financial expenditures broken down by task.

4) *Annual Technical Report* - This report is due as specified in the Cooperative Agreement, shall document the results of the complete effort. It shall contain brief information on each of the following:

1. A comparison of actual accomplishments with the goals and objectives established for the Cooperative Agreement, the findings of the investigator, or both.
2. Reasons why established goals were not met, if appropriate.
3. Other pertinent information

5) *Special Technical Report* - This report, due as required, shall document the results of a significant task, test, event or symposium.

6) *Final Technical Report* - This report, due 90 days after expiration or termination of the Cooperative Agreement, shall document the results of the complete effort. It shall contain brief information on each of the following:

a) A comparison of actual accomplishments with the goals and objectives established for the Cooperative Agreement, the findings of the investigator, or both.

b) Reasons why established goals were not met, if appropriate.

c) Other pertinent information.

7) *Financial Status Repor*t- shall be submitted on a Standard Form 425 "Federal Financial Report (FFR)" as follows.

a) Interim Status Report – This report is due within 90 days of the end of the interim reporting period (annually). The report shall be on a cash or accrual basis, depending on how the Recipient's accounting records are normally kept.

b) Final Financial Status Report - This report is due 90 days after completion of the Cooperative Agreement. The report shall be on a cash or accrual basis, depending on how the Recipient's accounting records are normally kept.

8) *Report of Federal Cash Transactions [applicable only to advance payment Cooperative Agreements]* – This report, due 15 days following the end of each quarter, shall be submitted on a Standard Form 425. The Recipient shall provide forecasts of Federal cash requirements in the "Remarks" section of the report.

6) Public Release or Dissemination of Information:

a) At this time, DARPA expects the work performed under this Cooperative Agreement to be fundamental research, and it is, therefore, not subject to publication restrictions. Papers resulting from unclassified contracted fundamental research are exempt from prepublication controls and requirements, pursuant to DoD Instruction 5230.27 dated October 6, 1987.

b) All papers resulting from this Cooperative Agreement will include the following

distribution statement: "Approved for public release; distribution is unlimited."

c) Should the character of the research change during Cooperative Agreement performance so that the research is no longer considered fundamental, the Cooperative Agreement will be modified to impose the restrictions on public release and dissemination of information that apply to those research efforts that are not considered fundamental research.

7) Acknowledgment of Sponsorship:

a) The Recipient agrees that in the release of information relating to this Cooperative Agreement, such release shall include a statement to the effect that (1) the project or effort depicted was or is sponsored by the Defense Advanced Research Projects Agency, (2) the content of the information does not necessarily reflect the position or the policy of the Government, and (3) no official endorsement should be inferred.

b) For the purpose of this article, information includes news releases, articles, manuscripts, brochures, advertisements, still and motion pictures, speeches, trade association proceedings, symposia, etc.

c) Nothing in the foregoing shall affect compliance with the requirements of the clause entitled "Security."

8) Intellectual Property Matters: Questions regarding intellectual property matters should be referred to the Agreements Officer (AO). All patent reports (interim and final) shall be submitted using the i-Edison.gov reporting website (http://s-edison.info.nih.gov/iEdison). In the event the Recipient is unable to submit reports through i-Edison, the Recipient may utilize DD Form 882, Report of Inventions and Subcontracts, for submission of interim and final invention reports. The DD Form 882 and all invention disclosures shall be submitted to the AO for proper disposition no later than 120 days after the end of the period of performance.

9) Activities Abroad: The Recipient shall assure that project activities carried on outside the United States are coordinated as necessary with appropriate Government authorities and that appropriate licenses, permits, or approvals are obtained prior to undertaking proposed activities. The awarding agency does not assume responsibility for Recipient compliance with the laws and regulations of the country in which the activities are to be conducted.

10) Security: The Recipient may not be granted access to classified information under this Cooperative Agreement. If security restrictions should happen to apply to certain aspects of the proposed research, the Recipient will be so informed. In the event that the scientific work under this Cooperative Agreement may need classification, or involve access to or storage of any classified data, the Government shall make its decision on the need to classify, or require such access or storage, within 30 days after receipt of written notice from the Recipient. If the decision is affirmative, the Government shall invoke the clause in reference to the "Termination"

proceedings in the DoD R&D general terms and conditions.

11) Research Involving Recombinant DNA Molecules: Any Recipient performing research involving recombinant DNA molecules and/or organisms and viruses containing recombinant DNA molecules agrees, by acceptance of this award, to comply with the National Institutes of Health "Guidelines for Research Involving Recombinant DNA Molecules," July 5, 1994 (59 FR 34496) as amended, or such later revision of those guidelines as may be published in the Federal Register.

12) Restrictions on Printing: Unless otherwise authorized in writing by the AO, reports, data, or other written material produced using funds provided by this Cooperative Agreement and submitted hereunder shall be reproduced only by duplicating processes and shall not exceed 5,000 single page reports or a total of 25,000 pages of a multiple page report. These restrictions do not preclude the writing, editing, and preparation of manuscript or reproducible copy of related illustrative materials if required as a part of this Cooperative Agreement, or incidental printing such as forms or materials necessary to be used by the Recipient to respond to the terms of the Cooperative Agreement. To satisfy the requirements of the Defense Technical Information Center, at least one copy of each technical report submitted to the Defense Technical Information Center must be black typing or reproduction of black on white paper or suitable for reproduction by photographic techniques. Reprints of published technical articles are not within the scope of this paragraph.

In accordance with Executive Order 12873, dated October 20, 1993, as amended by Executive Order 12995, dated March 25, 1996, the Recipient is encouraged to submit paper documents, such as letters or reports, that are printed/copied double-sided on recycled paper that has at least 30 percent postconsumer material.

13) Prohibition on Awarding to Entities that Require Certain Internal Confidentiality Agreements:

a) The Recipient shall not require employees, contractors, or subrecipients seeking to report fraud, waste, or abuse to sign or comply with internal confidentiality agreements or statements prohibiting or otherwise restricting such employees or contractors from lawfully reporting such waste, fraud, or abuse to a designated investigative or law enforcement representative of a Federal department or agency authorized to receive such information.

b) The Recipient must notify its employees, contractors, or subrecipients that the prohibitions and restrictions of any internal confidentiality agreements inconsistent with paragraph (a) of this award provision are no longer in effect.

c) The prohibition in paragraph (a) of this award provision does not contravene requirements applicable to any form issued by a Federal department or agency governing the nondisclosure of classified information.

d) If the Government determines that the Recipient is not in compliance with this award provision, it:

1) Will prohibit the Recipient's use of any funds under this award, in accordance with Federal appropriations law; and

2) May pursue other remedies available for the Recipient's material failure to comply with award terms and conditions.

14) Acceptance and Amendment of Cooperative Agreement:

1) The only method by which this Cooperative Agreement can be amended is by a formal, written amendment signed by the Agreements Officer. No other communications, whether oral or in writing, are valid.

2) The Recipient is not required to countersign the Cooperative Agreement document; however, the Recipient agrees to the conditions specified in the Research Cooperative Agreement Schedule and the Articles herein unless notice of disagreement is furnished to the Agreements Officer within 15 calendar days after the date of the Agreements Officer's signature.

In case of disagreement, the Recipient shall not assess the Cooperative Agreement of any costs of the research unless and until such disagreement(s) is/are resolved.

15) Live Organisms – Human and Animal Subjects:

a) Human Subjects. Cooperative Agreement funds may NOT be used for research that uses uninformed or nonvoluntary humans as experimental subjects. The Recipient is responsible for the protection of the rights and welfare of any human subjects involved in research, development, and related activities supported by this Cooperative Agreement. The Recipient agrees to comply with the Common Federal Policy for the Protection of Human Subjects, codified by the Department of Health and Human Services at 45 CFR part 46 implemented by the Department of Defense at 32 CFR part 219.

Department of the Interior/Interior Business Center (DOI/IBC) collaborates with the Institutional Review Board (IRB) and the U. S. Army Medical Research and Materiel Command (USAMRMC) for DARPA's Second-Level review. No work can be performed on human subjects without a Second-Level review and approval.

b) Animal Welfare. The Recipient shall register its research, development, test, and evaluation or training facility with the Secretary of Agriculture in accordance with 7 U.S.C. 2136 and 9 CFR subpart C, and section 2.30, unless otherwise exempt from this requirement by meeting the conditions in 7 U.S.C. 2136 and 9 CFR parts 1 through 4 for the duration of the activity. The Contractor shall have its proposed animal use approved in accordance with Department of Defense Instruction (DoDI) 3216.01, Use of Animals in DoD Programs, by a DoD Component Headquarters Oversight Office. The Contractor shall furnish evidence of such registration and approval to the Contracting Officer before beginning work under this agreement."

DOI/IBC collaborates with Institutional Animal Care and Use Committee (IACUC) for DARPA's Second-Level review. No work can be performed on animal subjects without a Second-Level review and approval.

The Recipient shall make its animals, and all premises, facilities, vehicles, equipment, and records that support animal care available during business hours and at other times mutually agreeable to the Contractor and the United States Department of Agriculture Office of Animal and Plant Health Inspection Service (USDA/APHIS) representative, personnel representing the DoD component oversight offices, as well as the Contracting Officer, to ascertain that the Contractor is compliant with 7 U.S.C. 2131-2159 and 9 CFR parts 1 through 4.

(1) The Recipient shall acquire animals in accordance with DoDI 3216.01, current at time of award (http://www.dtic.mil/whs/directives/corres/pdf/321601p.pdf).

(2) The Recipient agrees that the care and use of animals will conform with the pertinent laws of the United States, regulations of the Department of Agriculture, and policies and procedures of the Department of Defense (see 7 U.S.C. 2131 et seq., and 9 CFR subchapter A, parts 1 through 4, DoDI 3216.01, Army Regulation 40-33/ SECNAVINST 3900.38C/AFMAN 40-401(I)/DARPAINST 18/USUHSINST 3203). The Contractor shall also comply with DoDI 1322.24, Medical Readiness Training, if this contract includes acquisition of training.

(3) The Agreements Officer may immediately suspend, in whole or in part, work and further payments under this contract for failure to comply with the requirements of paragraphs (a) through (c) of this clause.

(1) The suspension will stay in effect until the Recipient complies with the requirements.

(2) Failure to complete corrective action within the time specified by the Contracting Officer may result in termination of this contract and, if applicable, removal of the Contractor's name from the approved vendor list for live animals used in medical training.

The recipient may request registration of its facility by contacting USDA/APHIS/AC, 4700 River Road, Unit 84, Riverdale, MD 20737-1234, or via the APHIS Animal Care website at: http://www.aphis.usda.gov/wps/portal/aphis/ourfocus/animalwelfare.

The Recipient shall include the substance of this clause, including this paragraph in all subcontracts involving research, development, test, and evaluation or training that use live vertebrate animals.

c) In the event a revised technical proposal with human or animal subject research is incorporated under this Cooperative Agreement, Recipient shall obtain all reviews and approvals prior to beginning any testing on humans or animals.

d) This article shall be flowed down to subcontractors, suitably modified to ensure that the recipient fully complies with this article.

16) Funding Increments and/or Options: The Recipient is advised that the Government's obligation to provide funding for funding increments and/or options included in the Cooperative Agreement is contingent upon (i) satisfactory performance and (ii) the availability of funds. Accordingly, no legal liability on the part of the Government exists unless or until (i) funds are made available to the Government and notice of such availability is confirmed in writing to the Recipient and (ii) performance of the research is deemed satisfactory in the judgment of the Agreements Officer.

17) Delegation of Administrative Duties: The administrative duties listed below have been delegated to the Office of Naval Research (ONR) identified in Item 7 of the Cooperative Agreement Schedule:

a) During performance:

1) Perform government furnished property administration.

2) Receive interim technical, cost/financial and patent reports from Recipient.

3) Review and adjudicate audit findings after receipt of the audit report and ensure that the recipient takes appropriate and timely corrective action, if required.

b) Upon expiration of agreement:

1) Receive final technical, cost/financial and patent reports from Recipient.

2) Obtain final government property report. Perform plant clearance, if required.

3) Assist the awarding Agreements Officer in resolving any questioned costs. Order audit from Department of Health and Human Services (DHHS), if applicable.

4) Perform cost sharing adjustments, if applicable.

5) Assure that all refunds due the Government are received.

6) Complete and submit to the awarding Agreements Officer a Completion Statement for this award.

18) Rights in Technical Data, Computer Software, and Copyright:

(a) Technical Data and Computer Software. Rights are as specified in 2CFR 200.315(d).

(b) Copyright. Rights are as specified in 2CFR 200.315(b).

19) Changes in Performance Period:

Recipient may initiate a one-time extension of the period of performance by up to 12 months unless one or more of the conditions outlined in subparagraphs a.-c. below apply. For one-time extensions, the Recipient must notify the Federal awarding agency in writing with the supporting reasons and revised period of performance at least 30 calendar days before the end of the period of performance specified in the award. This one-time extension may not be exercised merely for the purpose of using unobligated balances.

Extensions require explicit prior Federal awarding agency approval when:

a) The terms and conditions of the award prohibit the extension.

b) The extension requires additional Federal funds.

c) The extension involves any change in the approved objectives or scope of the project.

Montana State University - Bozeman
PREEMPT Program – Cooperative Agreement D18AC00031
Quarterly R&D Status Report

Period Covered by the Report: [Date] through [Date]

Date of Report:

Project Title: Preventing emergence and spillover of bat pathogens in high-risk global hotspots
Total Dollar Value: $8,239,511.00
Program Manager: Dr. James Gimlett, DARPA

Submitted by:
[PI Name]
[Institution]
[Address]

Telephone:
Email:

Subcontractors: [Co-PI name(s) and institution(s)]

TABLE OF CONTENTS

General notes:

- **Contact the program manager and team to report any financial or technical issues** (i.e., please do not wait until a report is due to bring up major issues).
- Clearly indicate if funding from another federal agency (e.g., NIH) has been used to support any data presented.
- Clearly indicate if any content is pre-publication sensitive or proprietary.
- Delete all instructional text from this document before submitting your report.
- Support your claims with data, images, and other evidence.
- Please update the header of each report with the respective quarterly period.
- Please use the following naming convention for report filenames: QR – PI institution – period covered (e.g., QR – University of XYZ – 01OCT2018 to 31DEC2018).
- Quarterly reports are due within 30 days of the quarter end date. For example, if the period ends on March 31, the report must be submitted by April 30.
- Monthly progress updates via conference calls will be scheduled with the program manager and his team.

Definitions:

- **Functional block diagram:** describes the functions and interrelationships of a system in a flock-block diagram style so that one can easily and thoroughly understand the system and the relationship of each of the parts to the whole. If the hardware evolves throughout your project, please provide a block diagram for each evolution (example included).
- **Work Breakdown Structure (WBS):** a hierarchical and incremental decomposition of the project into phases, deliverables and work packages. It is a tree structure that shows the subdivision of effort required to achieve an objective (example included).
- **Deliverable:** a measurable and verifiable outcome or object that a project team must create and deliver according to the terms of an agreement. An intangible deliverable is a particular outcome that the team achieves. A tangible deliverable is a concrete or material object created by the team.
- **Milestone:** a milestone describes the status of the project as represented by an event or moment at which one or more project activities are complete. Milestones can represent the completion of key project tasks, conclusions reached, or questions answered that affect project schedule significantly.
- **Major finding:** data with significant impact (positive or negative).
- **Metrics update:** progress (including delays and issues) toward achieving pre-established metrics of success.
- **SETA:** Science, Engineering, and Technical Assistant (internal DARPA term for technical support staff).

1 Progress Summary

1.1 Major Findings

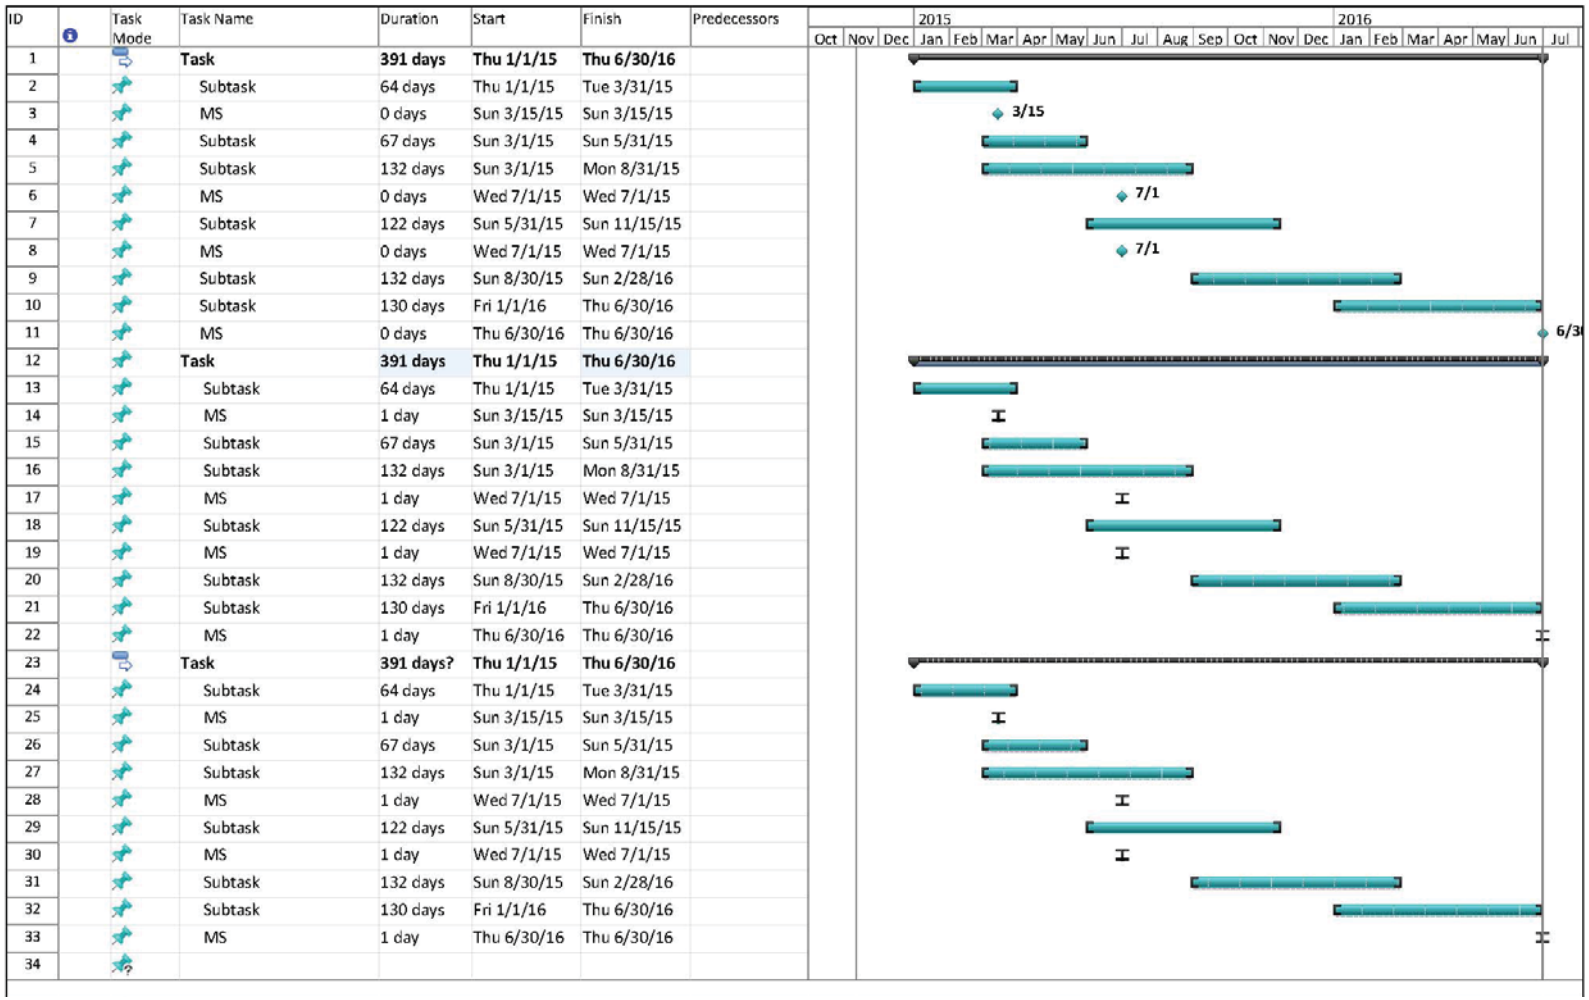
Briefly describe the most significant and salient accomplishment(s) achieved during the ***most recent quarter***. How has this compared to the original project plan?

1.2 Metrics Update

Accomplishment *Include associated task #*	**Month** *Planned vs. achieved*	**Update** *Provide current status, explain any schedule discrepancies, list next steps*

2 Schedule – Milestones and Deliverables

Provide a high-level Gantt chart for Phase I that includes all milestones and deliverables for each task. An example of an acceptable chart is shown below.



ID	Task Mode	Task Name	Duration	Start	Finish	Predecessors
1		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
2		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
3		MS	0 days	Sun 3/15/15	Sun 3/15/15	
4		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
5		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
6		MS	0 days	Wed 7/1/15	Wed 7/1/15	
7		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
8		MS	0 days	Wed 7/1/15	Wed 7/1/15	
9		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
10		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
11		MS	0 days	Thu 6/30/16	Thu 6/30/16	
12		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
13		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
14		MS	1 day	Sun 3/15/15	Sun 3/15/15	
15		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
16		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
17		MS	1 day	Wed 7/1/15	Wed 7/1/15	
18		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
19		MS	1 day	Wed 7/1/15	Wed 7/1/15	
20		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
21		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
22		MS	1 day	Thu 6/30/16	Thu 6/30/16	
23		**Task**	**391 days?**	**Thu 1/1/15**	**Thu 6/30/16**	
24		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
25		MS	1 day	Sun 3/15/15	Sun 3/15/15	
26		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
27		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
28		MS	1 day	Wed 7/1/15	Wed 7/1/15	
29		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
30		MS	1 day	Wed 7/1/15	Wed 7/1/15	
31		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
32		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
33		MS	1 day	Thu 6/30/16	Thu 6/30/16	
34						

Include a corresponding table that provides:

- Short text-identifier for each milestone/deliverable
- Team members associated with each
- Schedule status (provide explanation if behind schedule or significantly ahead of schedule)
- Description of how the milestone/deliverable is contingent or dependent on other parts of the effort (if applicable)

Milestone/ Deliverable	**Team member(s)**	**Due date**	**Date initiated**	**Date completed**	**Status**	**Dependencies** *Across tasks & team members*

3 Task Progress, Accomplishments, and Plans

*Please provide updates from the **most recent quarter**, not a cumulative discussion of the project to date. Support all claims with data. Highlight major accomplishments. Provide explanations and/or justifications for any deviation from the negotiated schedule and spending plan.*

Identify the following for each major task in your SOW; this section will form the bulk of your report:

- Task number (from SOW)
- High-level task description
- Completion status (e.g., ongoing, delayed, etc.)
- Funding associated with the task (spent to date vs. remaining to spend); explain any deviations from your original spend plan

Task #/Title	Brief Description	% Complete	Total $ for task	Spent	Remaining	Explain deviations from planned expenditures

- **Describe planned vs. actual progress towards the goals, milestones, and deliverables of the task; discuss why planned expectations were met, not met, or exceeded; highlight significant accomplishments**
- List next steps
- Support claims with data, images, or other evidence
- Identify and describe all significant challenges and risks encountered during work towards the goals of this task, including:
    - Critical dependencies across tasks and teams
    - Mitigation plan
    - Level of risk (high, medium, or low)
    - Changes in risk status since proposal or last report
    - Anticipated date risk will be resolved

4 Project Coordination, Dissemination, and Translation

4.1 Project Coordination

- Summarize key project planning and coordination over the quarter, including:
  - Meeting date(s), location, purpose
  - Attendees
  - Meeting outcomes, action items

4.2 Dissemination and Translation (if applicable)

- List any new partnerships, collaborators, users, etc.
- Describe potential commercialization pathways/partners

5 Publications and Presentations

Please provide a cumulative update on current and upcoming publications.

Title, Authors	Description/Type	Status
	Presentation to Conference Name	Published
	Paper, Name of Journal	Submitted
	Letter to the Editor, Scientific Organization	In preparation

6 Patents, Invention Disclosures, IDEs, etc…

Please provide a cumulative update of current or upcoming patents, inventions, Investigational Device Exemption (IDE), etc. Examples are listed in the table below.

Title, Authors	Description/Type	Status
	Patent; Name of Patent	Accepted
	FDA IDE	Filed/submitted
	Invention Disclosure	In preparation

Appendix I – Project Context

For future reports, only update this section if any information changes. Please indicate changes using red font.

Teaming and Personnel

Organizational Chart

Insert an organizational chart for your entire team

Contact Information

Please populate the following table with contact information for each team member. Please provide general area of expertise each will provide (e.g., microfluidics). In the last column, list tasks or otherwise briefly describe each individual's involvement in the effort.

Prime Team Members and Contact Information: [Institution]

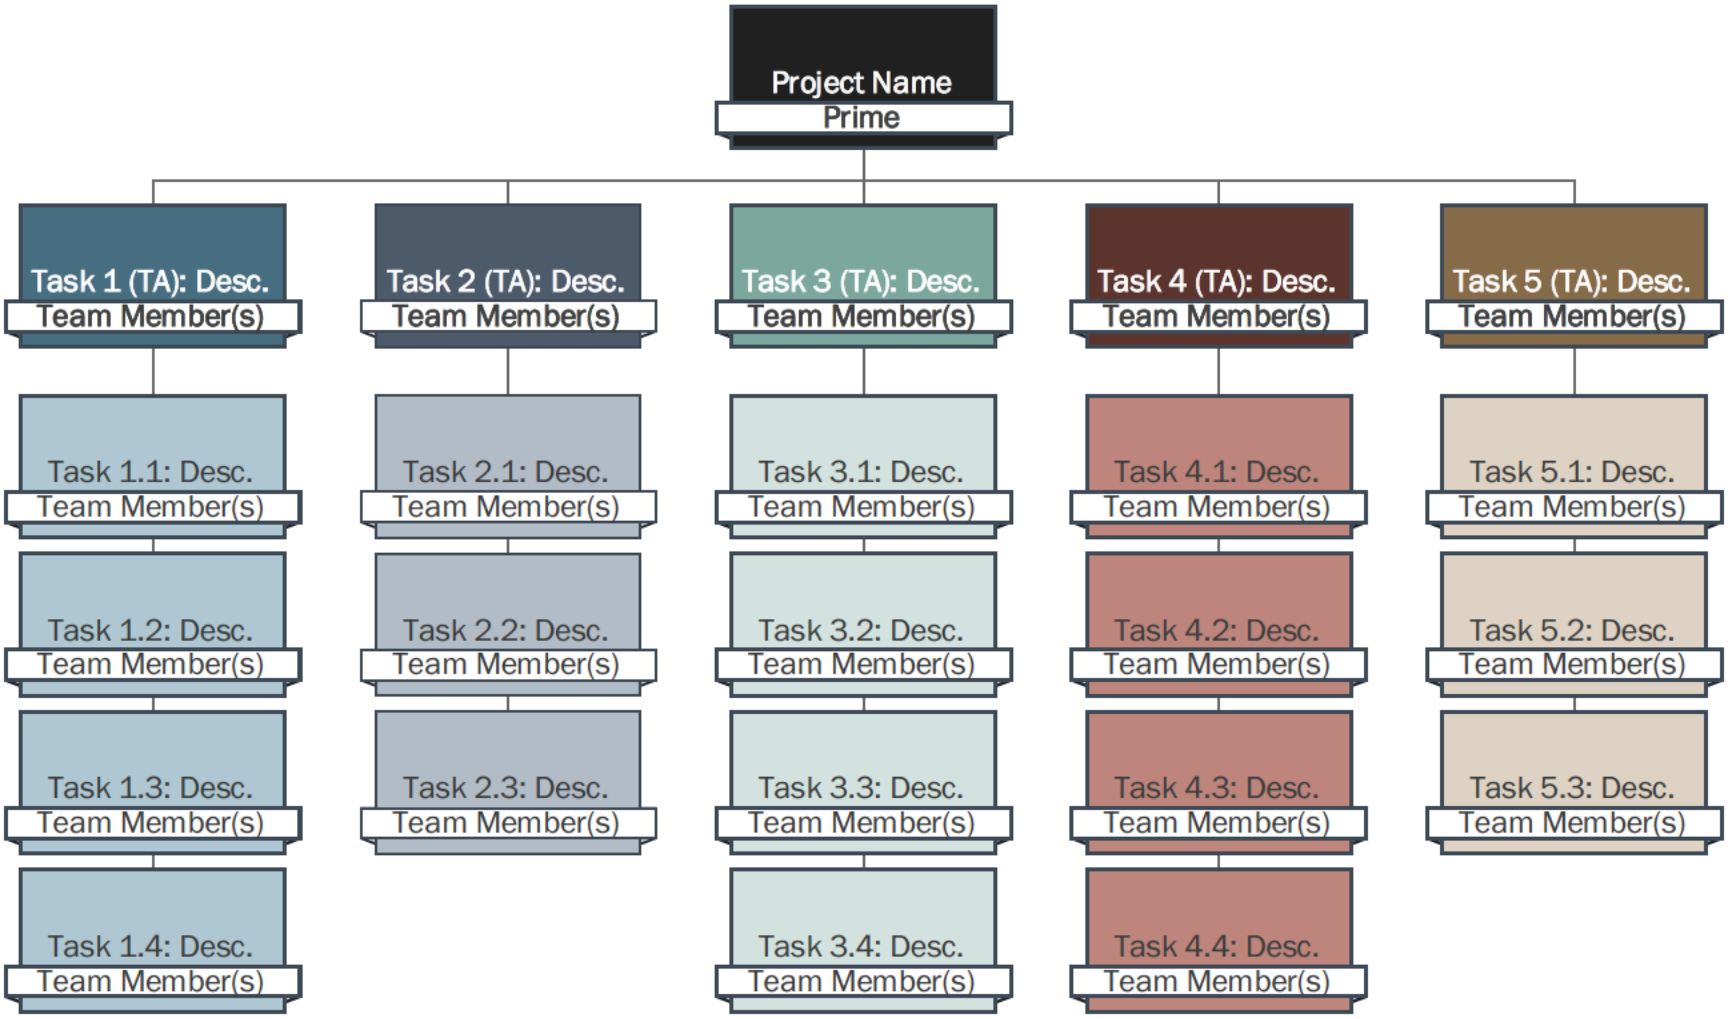
Role	Full name	Phone and email	Areas of Involvement
PI		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Subcontract Team Members and Contact Information: [Institution]

Role	Full name	Phone and email	Areas of Involvement
PI (expertise)		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Work Breakdown Structure

Provide breakdown of tasking and assigned team members as per the template shown below



Monthly Financial Report Template

LINK TO TEMPLATE (click here)

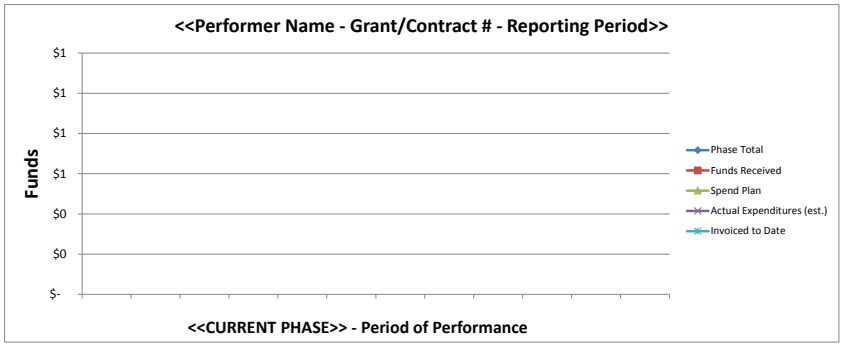
Please use this template to provide monthly financial updates to the PREEMPT team. As you input your data, the graph will automatically update. ***Please keep past reports in this file and create a new tab each month. We want to see all reports in the same file. Title tabs "Phase-Month-Year, " e.g., "Base - January - 2015"***

LINK TO EXAMPLE (click here)

An example of a completed template is also provided. The example graph illustrates a scenario where the performer is under spending. It is designed to show how this template will make it easy for INTERCEPT performers to clearly communicate the status of their effort to DARPA so that both can plan for and initiate contractual actions quickly and effectively.

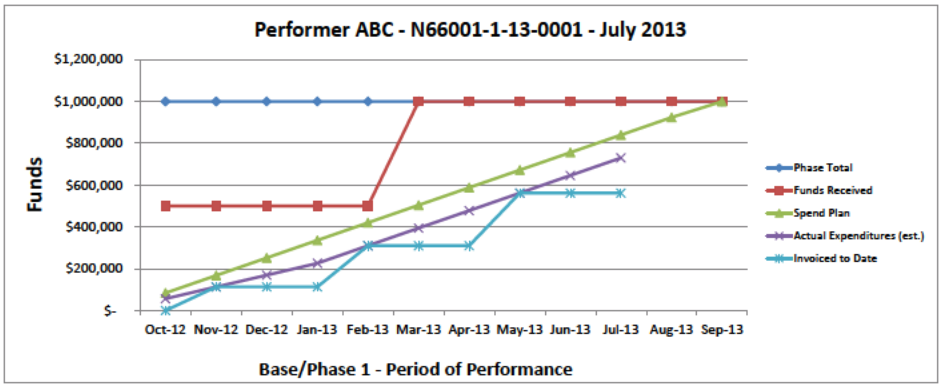
Spend Plan Data	
Period of Performance	The financial report will only cover the current phase (e.g., Base, Option 1, etc.). Use a format similar to "Sep-2013," not "Month 6." In order to plan for continuing resolution requests, DARPA may reach out to you separately to request your projected spend rate for future phases.
Phase Total	Total for current phase *(Example Graph - total is $1,000,000)* .
Funds Received	Funds awarded to date; most efforts are funded incrementally *(Example Graph - this effort received an increment for $500,000 in Oct-2012 to exercise the base, and received the remainder of their base period funding in Mar-2013 (remaining $500,000))* .
Spend Plan	Projected Expenditures must cover the entire phase.
Actual Expenditures (est.)	Actual Expenditures should not be solely based off of invoices you have submitted or received to date. Instead, it should be an accurate (to the extent that is possible) account of the expenses you have actually incurred to date. For example, if a subcontractor has incurred but hasn't invoiced $100,000 worth of work, include the $100,000 in your actual expenditures. Or a large amount of equipment valued at $50,000 that hasn't yet been invoiced should also be factored in to the actual expenditures.
Invoiced to Date	Report the invoices you have submitted to date *(Example Graph - the scenario used in the example graph submits invoices quarterly)* .
Issues/Updates Summary (if applicable)	
Use this section as an opportunity to bring issues, concerns, or updates to the attention of DARPA. For example, you can summarize reasons for over/under-spending, potential no-cost extension requests, invoicing problems, etc.	

***Amounts for Spend Plan, Actual expenditures, Invoiced to Date are cumulative.



Spend Plan Data												
Period of Performance (Current Phase Only)												
Phase Total												
Funds Received												
Spend Plan												
Actual Expenditures (est.)												
Invoiced to Date												

Issues/Updates Summary (if applicable)



Spend Plan Data

Invoiced to Date	$ -	$ 113,000	$ 113,000	$ 113,000	$ 310,100	$ 310,100	$ 310,100	$ 562,100	$ 562,100	$ 562,100		

Issues/Updates Summary (if applicable)

We anticipate that we will need to request a four-month no cost extension (NCE). The NCE is necessary due to delays we experienced while getting Subcontractor #1 under contract. Although our effort's period of performance began in October 2012, the subcontract was finalized and fully-executed in February 2013, which resulted in a four-month delay from the intended start date. Subcontractor #1 is conducting a 12-month study, and cannot speed up their experiments. We would, however, like to begin work on Option 1. We intend to perform these tasks in parallel to the extended Base Period tasks (which are primarily performed by Subcontractor #1).

Preventing emergence and spillover of bat viruses in high-risk global hotspots

STATEMENT OF WORK

July 17th 2018

Milestones by Task

CIES: Cary Institute of Ecosystem Studies; **CSU**: Colorado State University; **Cornell**: Cornell University; **GU**: Griffith University; **JH**: Johns Hopkins University; **MSU: Montana State University**; **PSU**: Penn State University; **RML**: Rocky Mountain Laboratories; **TTU**: Texas Tech University; **UCB**: University of California, Berkeley; **UCLA**: University of California, Los Angeles; **Cambridge**: University of Cambridge.

Note that Rocky Mountain Laboratories (RML) is funded separately by DARPA via IAA/MIPR to NIAID.

TA1

COLLECT AND ANALYZE FIELD SAMPLES

Task 11.01, Data collection: longitudinal sampling of wild bat populations and a captive population. Cambridge, GU, JH, and UCB, with assistance from MSU and TTU, will sample multiple bat populations longitudinally in multiple locations and ship retrospective bat samples to RML or local laboratory for analyses (11.03).

Task 11.02, Data collection: retrospective analysis of bat samples. Cambridge, GU, JH, and UCB will identify, locate, and ship retrospective bat samples to RML or local laboratory for analyses (11.03).

Task 11.03, Lab: screening, metagenomics to identify virus and quasispecies. RML and Cambridge or local laboratory will screen and sequence samples from bats; create a list of sequences that have spilled over from bats to other species; and select sequences for genotype-phenotype modeling.

Task 11.12, Lab: screening retrospective samples from human/domestic livestock hosts. Cambridge, JH, and UCB will identify, locate, and ship retrospective human/livestock samples to RML or local laboratory for analysis; RML or local laboratory will screen samples and create a list of sequences that have spilled over from bats to other species.

Milestones

Australia (GU will do field collection and RML or local laboratory will do sequencing):

- Establish field sites and train field teams (6mths)
- Sample up to 40 bats in 4 bat colonies monthly for 2 years (12mths, 24mths)
- Respond to spillover events or viral pulses within the study area by sampling adaptively until prevalence decreases (12mths, 24mths)
- PCR on all samples for Hendra virus (30mths)
- Sequence all positive samples available (36mths)
- Analyze 1000 retrospective bat samples for henipaviruses (24mths).

Bangladesh (JH will do field collection and in-country PCR; RML will do sequencing):

- Sample up to 40 bats in 4 colonies monthly for 2 years (24mths)
- Respond to spillover events or viral pulses by sampling adaptively until prevalence decreases (24mths)
- PCR on samples for Nipah virus (30mths)
- Sequence all positive samples available (36mths)
- Analyze retrospective bat samples for henipaviruses (24mths).

Ghana (Cambridge will do field collection and laboratory analyses, with some help from RML):

- Locate retrospective human and animal samples suitable for testing and establish sequencing pipeline (6 months)
- Sample up to 120 bats per quarter in 3 colonies, perform PCR testing on the first batches and send positive sample for sequencing (12 months)
- Update sampling effort in bat colonies for year 2 based on 12 months result, for PCR and sequencing, with up to 500 bats to be caught in year 2 (24mths)
- Sample bats in the captive colony every 3 months (24mths)
- Sequence all positive samples available (36mths)

Madagascar (UCB will do field collection and PCR, and RML or local laboratory will do sequencing):

- Establish field sites and train field teams (12mths)
- Sample up to 30 bats in 3 colonies monthly for 2 years (12 mths, 24mths)
- Respond to viral pulses by sampling adaptively until prevalence decreases (12 mth, 24mths)
- Analyze 700 retrospective bat samples for henipaviruses (12mths)
- PCR on samples from bats at Institut Pasteur de Madagascar (30mths)
- Sequence all positive samples available (36mths)

Historic humans and livestock samples (JH, Cambridge, UCB):

- Identify and ship historic samples to RML or local laboratory (6mths)
- PCR on samples from humans and livestock (12mths)
- Sequencing of all positive samples available (18mths)

IDENTIFY HOST IMMUNE SIGNATURES

Task 11.04 Lab: identify host immune and stress signatures in wild bats and in a captive feeding trial. MSU, with help from CSU will measure bat immune signatures. TTU will measure bat stress signatures and nutritional status. A captive feeding trial will be conducted in Ghana (Cambridge), or alternatively, if a natural nutritional stress event occurs in Australia during Phase I, this trial will be conducted in Australia (GU).

Milestones

Immunology on samples from Australia (MSU):

- Validate and optimize tests for each bat species (6mths)
- Immunological markers such as IgG and IgA, biomarkers of cell damage, gene expression of antiviral & proinflammatory proteins, and microbial killing assays for 400 samples (30mths)

Immunology on samples from Ghana (Cambridge):

- Titrate antibodies against Henipaviruses in sera from all PCR-positive bats and a sample of up to 1000 PCR-negative bats, from wild and captive colonies (24 mths).

Stress signatures on samples from Australia (TTU):

- Test up to 720 hair and fecal samples for cortisol (30mths)
- Develop methodology to use bioelectrical impedance analysis to measure body condition of bats (12mths)
- Measure body condition of 400 bats (24mths)

Captive feeding trial (Cambridge, GU)

- Conduct experimental diet manipulation to test the effect of nutritional status on immune state and viral shedding (30mths)

COLLECT ENVIRONMENTAL, ECOLOGICAL, and RESERVOIR HOST DATA

Task 11.10 Remote sensing data, longitudinal short-term weather and long-term climate data, land cover change, human population data, bat movement data. PSU will identify environmental drivers of shedding in Australia and detect large bat colonies through remote sensing. TTU will implement bat telemetry.

Milestones

Remote sensing (PSU):

- Collect data on weather, climate, and land cover change in Australia (24mths)
- Collect data on human population dynamics across space (local/region), time (seasonal/decadal) (24mths)

Bat movement data (TTU):

- Deploy GPS tracking devices on bats in resident and nomadic colonies in Australia (12mths, half deployed; 24mths all deployed)
- Collect, collate, and analyze bat movement data (36mths)

CREATE GENOTYPE-PHENOTYPE MAPS FOR HENIPAVIRUS QUASISPECIES BASED ON *IN VITRO* AND *IN VIVO* WORK

Task 11.13, Lab: in vitro experiments to assess jump potential of quasispecies to new hosts. Cornell and RML will quantify determinants of zoonotic potential for henipavirus strains and quasispecies.

Milestones

Cloning (Cornell; 24 mths):

- Prioritize sequences for 20 F and G pairs to be analyzed for receptor binding and membrane fusion (24mths)
- Synthesize and clone sequences for 20 F and G gene pairs in pCAGGS plasmids (24mths)
- Grow plasmids in bacteria for 20 pairs F and G pairs (24mths)

Receptor binding and membrane fusion assays (Cornell, with help from RML; year 2, 12mths)

- Complete receptor binding assays for 20 G sequences (year 2, 12 months)
- Complete membrane fusion assays in 3 cell lines (human, bat and pig) (year 2, 12 months)

Molecular docking with *in silico* with *in vitro* measurements (RML, with help from Cornell):

- Perform molecular docking analyses (24mths)

Task 11.08, Lab: amplification and transmission dynamics of quasispecies *in vitro* and *in vivo*. RML, with help from CSU, will undertake in vivo experiments to measure phenotypes of henipavirus strains.

Milestones

In vitro and *in vivo* work (RML):

- Use cell culture experiments to analyze growth kinetics of henipaviruses (12mths)
- Develop hamster model for infection experiments (24mths)
- Conduct infection experiments in hamster model to measure infection, shedding, & QS in model hosts (24mths)
- Compare pathogenicity and transmission characteristics in hamster studies with historic studies done by RML (30mths)
- Obtain lung samples at peak virus replication and deep sequence these samples to study QS and selective pressures in a dead-end host (30mths)
- Develop bat models for henipavirus strains with highly pathogenic characteristics in the dead-end host model (36mths)
- Conduct infection experiments and measure infection and shedding in bats (36mths)
- Upon sufficient shedding, conduct contact transmission experiments (36mths)

- Analyze inoculated vs. transmitted virus populations by deep sequencing and identify potential transmissible QS (36mths)
- Analyze QS by established long-read PCR NSG methods (ongoing 42mths)

ANALYZE DATA

Task 11.05, Data analysis: statistical analysis of field data, lab data, environmental and ecological data, and bioinformatics NGS data. Provide statistical support and manage database for project.

Milestones

Data analysis and support (MSU):

- Develop a database structure, system and procedures for providing access to data, and a data visualization platform to facilitate information sharing across tasks and institutions (12mths)
- Clean and check data as it arrives (ongoing over 24mths)
- Graphically visualize and share incoming data for full team (ongoing over 24mths)
- Manage database, analyze data as appropriate, and provide statistical support to the team (ongoing 42mths)

Specific analyses to support other Tasks:

- Use statistical modeling to investigate and quantify links among nutritional status (TTU), stress signatures (TTU), immune status (MSU) and viral shedding (GU/RML/local laboratory) in *wild Australian bats* (30 months)
- Use statistical modeling to investigate and quantify links among nutritional status (Cambridge), stress signatures (MSU), immune status (Cambridge) and viral shedding (Cambridge) *in captive bats* (42 months)

DEVELOP MODELS

Task 11.06, Stochastic models of within- and between-host virus dynamics in bats. Cambridge, with help from GU, will perform stochastic modeling of within and between host virus dynamics in bats.

Milestones

Modeling (Cambridge, GU):

- Develop models of virus transmission within bat populations using prior knowledge from each location (12mths)
- Develop generic models of within-host virus dynamics that incorporate measurable components of the bat immune system (12mths)
- Validate and refine within- and between-host models of virus dynamics in bats using data collected in each field site and laboratory (36mths)

Task 11.15, Mechanistic mathematical modeling of viral fitness within humans, bats, and other host species, iterated with lab studies. UCLA will assemble genotype-to-phenotype maps for reservoir and spillover host species.

Milestones
Viral fitness modeling (UCLA):

- Develop mechanistic model of viral life cycle within cells (12mths)
- Integrate molecular, virologic, cell culture, and animal experiment data (24mths)
- Compare fitness predictions from *in silico* vs *in vitro* data (36mths)
- Integrate models and lab data to establish empirical relations between viral traits and fitness (42mths)

Task 11.09, Phylodynamic models of quasispecies dynamics within bat populations and between host species. MSU, with help from Cambridge and UCLA, will perform phylodynamic modeling of henipaviruses in bat populations.

Milestones
Phylodynamic modeling (MSU, Cambridge, UCLA):

- Formulate model framework to link viral genetics to transmission dynamics (12mths)
- Create models of within- and between-host selection in bat populations (24mths)

Task 12.02, Multi-scale models of zoonotic transmission from bats to humans to predict quasispecies expansions and pulses of excretion. Cambridge, with help from MSU, UCLA and GU, will develop a multi-scale mechanistic modeling framework for pathogen spillover.

Milestones
Multi-scale modeling (Cambridge, MSU, UCLA, GU):

- Develop baseline tools to relate spillover modeling framework from Plowright et al. to field data (12mths)
- Adapt spillover modeling framework from Plowright et al. to henipavirus contexts; identify key challenges to operationalize (18mths)
- Integrate bat virus transmission dynamics, environmental data. and viral fitness models (30mths)
- Develop an integrative model of bat virus spillover that is operationalized to predict probability of spillover at a spatial and temporal scale relevant for intervention (42mths)
- Perform a two-step validation of models:
    - Internal validation of the fitting methods: using simulated data generated by our candidate models, we will infer the parameter values and check the accuracy and precision of the fitting method (ongoing over 42mths)
    - External validation: we will exclude parts of the data iteratively, fit the models to the remaining dataset and check that it predicts correct values for the missing data (ongoing over 42mths)

Task 11.16, Machine learning to ID virus, reservoir traits, zoonotic risk. CIES will perform machine learning analyses to prioritize surveillance by identifying combinations of bat traits and environmental factors that predict spillover.

Milestones

Machine learning analyses (CIES): (all activities below are ongoing over 36mths)

- Collate and pre-process multiple data streams from field teams (environmental data; ecological data on bat populations; data on human ecology)
- Engineer features; impute bat trait data; tune hyperparameters for selected machine learning algorithm; execute cross-validation and target shuffling procedures to diagnose and correct overfitting; produce trait profiles of bat species predicted to be henipavirus positive (first predictions at 6mths).
- Repeat procedures above for models at the ecoregion and country scales (ongoing over 36mths)
- Combine species-level predictions with environmental and human ecological features from the Australian system (i.e., corresponding with viral shedding pulses in local bat populations, satellite imagery on seasonal human population densities, fruiting phenology, climate induced stress). Identify bat species that present the greatest spillover risk to humans, and measurable features that best predict viral shedding (ongoing over 24mths)
- Incorporate data on viral shedding events and conduct machine learning on viral PCR data to identify detectable predictors of viral shedding (Phase 2)
- Assess features corresponding to parameters in a multiscale mechanistic model of viral shedding and provide machine learning support of features to be included in multi-scale models of viral dynamics (e.g., engineering features, estimating parameters impacting viral shedding) (ongoing over 18 months in Phase 2)

TA2

DEMONSTRATE PROOF OF CONCEPT FOR AN ECOLOGICAL INTERVENTION FOR SPILLOVER

Task 22.03, Proof-of-concept for preemption through strategic ecological interventions. GU, with help from TTU and PSU, will do preliminary studies to develop the proof-of-concept demonstration of an ecological intervention to stop spillover. GU, MSU, TTU, Cambridge, CIES, CSU, PSU, RML will all contribute to investigating links between nutritional stress and virus shedding (above).

Milestones.

Demonstrate that bats move from urban roosts to flowering events in native forests (GU, with help from TTU)

- Establish methodology for using movement data to validate bats moving from urban roosts to native forests (6mths)
- Acquire movement data from existing and projected sources (18mths)
- Analyse movement data (24mths).

Demonstrate that bats locate and feed in regenerated habitat

- Develop experimental design and field methods to test use of regenerated forest as feeding habitat by bats (6mths)
- Establish field sites for testing use of regenerated forest as feeding habitat and commence field sampling (12mths)
- Sample up to 30 paired regeneration sites and remnant native habitat (control) sites for feeding bats (18mths)
- Analyse feeding data (24mths)

DEMONSTRATE PROOF OF CONCEPT, FEASIBILITY, AND SCALABILITY OF CHAD/VSV VACCINATION

Task 22.02, Proof-of-concept demonstration of ChAd/VSV vaccination feasibility and scalability of ChAd/VSV vaccination in bats. RML will develop and test a scalable vectored vaccine for target henipaviruses in bats. RML, with help from Cambridge, will assess the feasibility and scalability of the vaccine in bats.

Milestones

Vaccine development (RML):

- Design novel vaccines based on TA1
- Test by comparing measures of protection with historic hamster models (12mths)
- Test the effectiveness of the vaccines against novel henipaviruses (24mths)
- Demonstrate reduced probability of virus transmission among bats and among bats and recipient host species *in vivo* (42mths)
- Quantify scalability of ChAd/VSV vaccination in captive bats in Ghana (42mths)

TRANSITION PLAN

MSU and RML will develop the research transition plan.

Milestones

- Work with the MSU technology transfer infrastructure and personnel, and with the CEPI program to develop partnerships with vaccine manufacturers (30mths)
- Developed an inter-institutional agreement to enable the transfer of our discoveries to industry for commercialization (36mths)

RESEARCH COOPERATIVE AGREEMENT SCHEDULE

1. **Agreement Number**: **D18AC00031** **Amendment 0001**

2. **Recipient Name:** **Montana State University - Bozeman**
307 Montana Hall
Bozeman, MT 59717

3. **Identification Numbers**:

Tax Identification Number (TIN)**: 81-6010045**

Data Universal Numbering System (DUNS) Number**: 625447982**

Commercial and Government Entity (CAGE) Code**: 1KQE9**

Federal Interagency Code for Education (FICE)**: 002532**

Catalog of Federal Domestic Assistance (CFDA): **12.910 – Research and Technology Development**

ASAP Recipient Number: **3034514**

4. **Principal Investigator/Key Personnel**: Dr. Raina Plowright
111A Lewis Hall
P.O. Box 173520
Bozeman, MT 59717-3520

Telephone:
E-mail address:

5. The purpose of this amendment is as follows:

a. Correct the ADPM to Phillip Lamp at Points of Contact 6. e.
b. Update the Quarterly R&D Status and the Monthly Financial Management Report due dates at 14. Reporting Requirements.

6. **Item 6 - Points of Contact is hereby updated as follows:**

6. Points of Contact:

a. Agreements Officer: Department of the Interior
Interior Business Center

Acquisition Services Directorate, Division III
354 South Highway 92
Sierra Vista, AZ 85635

Attention: Doreen Vieira-Cross
Telephone:
FAX:
Email:

b. Cooperative Agreement Administrator:

Department of the Interior
Interior Business Center
Acquisition Services Directorate, Division III
354 South Highway 92
Sierra Vista, AZ 85635

Attention: Deborah Branham

7. Item 14 – Reporting Requirements is hereby updated as follows:

14. Reporting Requirements: A final DD Form 882 is required to be filed listing all subject inventions or stating that there were none. In accordance with DARPA-BAA-HR001118S0017, the frequency of the reporting requirement differs from those commonly found in financial assistance agreements due to significant Government involvement throughout the duration of the research cycle. The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 45 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 45 days of the end of each month	See Exhibit A Attachment 2
Special Technical Report	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2019 29 Dec 2020	AOR, AO, PM, ONR & DARPA Research Services
Final Technical Report	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 Dec 2020	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	28 Jan 2021	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

If Optional Phase II is implemented - The following reports shall be submitted and will become due on the dates as shown below:

REPORT TYPE	DUE DATE	SUBMIT TO
Quarterly R&D Status Reports	Within 45 days of the end of each quarter	See Exhibit A Attachment 1
Monthly Financial Management Report	Within 45 days of the end of each month	See Exhibit A Attachment 2
Special Technical Reports	Due as required	AOR, AO, PM, & DARPA Research Services
Annual Federal Financial Report (SF 425)	29 Dec 2021	AOR, AO, PM, ONR, & DARPA Research Services
Final Technical Report	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Financial Report (SF425)	29 JUN 2022	AOR, AO, PM, ONR, DTIC*, & DARPA Research Services
Final Invention Report (DD Form 882)	29 JUL 2022	See Exhibit A Article 8 - Intellectual Property Matters

*Defense Technical Information Center
ATTN: DTIC-O
8725 John J. Kingman Road
Ft. Belvoir, VA 22060-6218

8. Acceptance of this amendment is pursuant to Article 14 Acceptance and Amendment of Cooperative Agreement Exhibit A.

9. All other terms and conditions remain unchanged.

THIS ACTION IS MADE ON BEHALF OF A DoD CUSTOMER UTILIZING DoD FUNDS.

Records: As required by Uniform Guidance, 2 CFR 200, or 45 CFR Part 75, SUBRECIPIENT will maintain appropriate and complete accounts, records, documents and other evidence showing and supporting all costs incurred under this agreement. Subrecipient must retain all records that are required by the terms of the prime award or may reasonably be considered pertinent to the prime award. PTE may verify all expenditure receipts and disburse funds in an amount equal to the approved expenditures. SUBRECIPIENT will allow access to PTE, the Montana Legislative Auditor and/or the Montana Legislative Fiscal Analyst, or other designated persons to all records as may be necessary for audit purposes and to determine compliance with this agreement.

Fly America Act: The Fly America Act requires that all travelers and others performing U.S. Government-financed air travel use U.S. flag carriers to the extent such carriers are available, even if their use would cost more. Even when the entire trip cannot be made on U.S. flag carriers to the extent possible they should be used to the farthest interchange point on a usually traveled route. 301-3.6 (b)(4)(ii). Chartered flights are also subject to the requirements. Cost of duties, visas and value added tax are unallowable. Receipts of travel expenses are required to be submitted for payment.

Liability Exposure: The parties understand and agree that the liability of the State of Montana, PTE, its officials and employees is controlled and limited by the provisions of Title 02, Chapter 09, Montana Code Annotated entitled, *Government Structure and Administration – Liability Exposure and Insurance Coverage*, and the provisions of Title 18, Chapter 01, Part 4 entitled, *Contract Actions Against the State*. Any provision of this agreement, whether or not incorporated herein by reference or otherwise, will be controlled, limited and otherwise modified to limit any liability of the State of Montana, PTE, its officials and employees to that set forth in the above cited laws.

Non-Discrimination: SUBRECIPIENT agrees that no part of this subaward will be performed in a manner which illegally discriminates against any person on the basis of race, color, religion, creed, political ideas, national origin, sex, age, marital status, physical and/or mental handicap.

Assignment Transfer and Subcontracting: There will be no assignment, transfer, or subcontracting of this agreement, or of any interest in this agreement, unless both parties agree in writing. No services required under this agreement may be performed by individuals not subject to this agreement unless both parties agree in writing.

Use of Names: Neither party will include the name of the other party or any of its employees in any advertising, sales promotion or other publicity matter without the prior written consent of the other party.

Reporting Requirements: SUBRECIPIENT will provide to PTE any requested reports necessary to the completion of the prime award, and as detailed in **Attachment 4A.**

Attachment 4A
Subaward Agreement Additional Reporting Requirements

Quarterly R& D Status Reports will be submitted within thirty (30) days after the end of each project quarter (3/31, 6/30, 9/30, and 12/31) to the Pass-through Entity's Principal Investigator identified in Attachment 3. See Exhibit A Attachment 1 for format and instructions.

Monthly Financial Management Report reports will be submitted to the Pass-through Entity's Principal Investigator identified in Attachment 3, within thirty (30) days of the end of the month. See Exhibit A Attachment 2 for format, instructions and example.

Special Technical Reports as requested by DARPA/DOI, due as required, will be submitted when requested by the Pass-through Entity's Principal Investigator identified in Attachment 3.

Final Invention Report (DD Form 882) will be submitted to the Pass-through Entity's Principal Investigator identified in Attachment 3 by 12/20/2020. See Exhibit A Attachment 3 for format and instructions.

TABLE OF CONTENTS

General notes:

- **Contact the program manager and team to report any financial or technical issues** (i.e., please do not wait until a report is due to bring up major issues).
- Clearly indicate if funding from another federal agency (e.g., NIH) has been used to support any data presented.
- Clearly indicate if any content is pre-publication sensitive or proprietary.
- Delete all instructional text from this document before submitting your report.
- Support your claims with data, images, and other evidence.
- Please update the header of each report with the respective quarterly period.
- Please use the following naming convention for report filenames: QR – PI institution – period covered (e.g., QR – University of XYZ – 01OCT2018 to 31DEC2018).
- Quarterly reports are due within 30 days of the quarter end date. For example, if the period ends on March 31, the report must be submitted by April 30.
- Monthly progress updates via conference calls will be scheduled with the program manager and his team.

Definitions:

- **Functional block diagram:** describes the functions and interrelationships of a system in a flock-block diagram style so that one can easily and thoroughly understand the system and the relationship of each of the parts to the whole. If the hardware evolves throughout your project, please provide a block diagram for each evolution (example included).
- **Work Breakdown Structure (WBS):** a hierarchical and incremental decomposition of the project into phases, deliverables and work packages. It is a tree structure that shows the subdivision of effort required to achieve an objective (example included).
- **Deliverable:** a measurable and verifiable outcome or object that a project team must create and deliver according to the terms of an agreement. An intangible deliverable is a particular outcome that the team achieves. A tangible deliverable is a concrete or material object created by the team.
- **Milestone:** a milestone describes the status of the project as represented by an event or moment at which one or more project activities are complete. Milestones can represent the completion of key project tasks, conclusions reached, or questions answered that affect project schedule significantly.
- **Major finding:** data with significant impact (positive or negative).
- **Metrics update:** progress (including delays and issues) toward achieving pre-established metrics of success.
- **SETA:** Science, Engineering, and Technical Assistant (internal DARPA term for technical support staff).

1 Progress Summary

1.1 Major Findings

Briefly describe the most significant and salient accomplishment(s) achieved during the ***most recent quarter***. How has this compared to the original project plan?

1.2 Metrics Update

Accomplishment *Include associated task #*	**Month** *Planned vs. achieved*	**Update** *Provide current status, explain any schedule discrepancies, list next steps*

2 Schedule – Milestones and Deliverables

Provide a high-level Gantt chart for Phase I that includes all milestones and deliverables for each task. An example of an acceptable chart is shown below.

ID	Task Mode	Task Name	Duration	Start	Finish	Predecessors
1		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
2		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
3		MS	0 days	Sun 3/15/15	Sun 3/15/15	
4		Subtask	67 days	Sun 3/1/15	Sun 5/31/15	
5		Subtask	132 days	Sun 3/1/15	Mon 8/31/15	
6		MS	0 days	Wed 7/1/15	Wed 7/1/15	
7		Subtask	122 days	Sun 5/31/15	Sun 11/15/15	
8		MS	0 days	Wed 7/1/15	Wed 7/1/15	
9		Subtask	132 days	Sun 8/30/15	Sun 2/28/16	
10		Subtask	130 days	Fri 1/1/16	Thu 6/30/16	
11		MS	0 days	Thu 6/30/16	Thu 6/30/16	
12		**Task**	**391 days**	**Thu 1/1/15**	**Thu 6/30/16**	
13		Subtask	64 days	Thu 1/1/15	Tue 3/31/15	
14		MS	1 day	Sun 3/15/15	Sun 3/15/15

Include a corresponding table that provides:

- Short text-identifier for each milestone/deliverable
- Team members associated with each
- Schedule status (provide explanation if behind schedule or significantly ahead of schedule)
- Description of how the milestone/deliverable is contingent or dependent on other parts of the effort (if applicable)

Milestone/ Deliverable	**Team member(s)**	**Due date**	**Date initiated**	**Date completed**	**Status**	**Dependencies** *Across tasks & team members*

3 Task Progress, Accomplishments, and Plans

*Please provide updates from the **most recent quarter**, not a cumulative discussion of the project to date. Support all claims with data. Highlight major accomplishments. Provide explanations and/or justifications for any deviation from the negotiated schedule and spending plan.*

Identify the following for each major task in your SOW; this section will form the bulk of your report:

- Task number (from SOW)
- High-level task description
- Completion status (e.g., ongoing, delayed, etc.)
- Funding associated with the task (spent to date vs. remaining to spend); explain any deviations from your original spend plan

Task #/Title	Brief Description	% Complete	Total $ for task	Spent	Remaining	Explain deviations from planned expenditures

- **Describe planned vs. actual progress towards the goals, milestones, and deliverables of the task; discuss why planned expectations were met, not met, or exceeded; highlight significant accomplishments**
- List next steps
- Support claims with data, images, or other evidence
- Identify and describe all significant challenges and risks encountered during work towards the goals of this task, including:
    - Critical dependencies across tasks and teams
    - Mitigation plan
    - Level of risk (high, medium, or low)
    - Changes in risk status since proposal or last report
    - Anticipated date risk will be resolved

4 Project Coordination, Dissemination, and Translation

4.1 Project Coordination

- Summarize key project planning and coordination over the quarter, including:
  - Meeting date(s), location, purpose
  - Attendees
  - Meeting outcomes, action items

4.2 Dissemination and Translation (if applicable)

- List any new partnerships, collaborators, users, etc.
- Describe potential commercialization pathways/partners

5 Publications and Presentations

Please provide a cumulative update on current and upcoming publications.

Title, Authors	Description/Type	Status
	Presentation to Conference Name	Published
	Paper, Name of Journal	Submitted
	Letter to the Editor, Scientific Organization	In preparation

6 Patents, Invention Disclosures, IDEs, etc…

Please provide a cumulative update of current or upcoming patents, inventions, Investigational Device Exemption (IDE), etc. Examples are listed in the table below.

Title, Authors	Description/Type	Status
	Patent; Name of Patent	Accepted
	FDA IDE	Filed/submitted
	Invention Disclosure	In preparation

Appendix I – Project Context

For future reports, only update this section if any information changes. Please indicate changes using red font.

Teaming and Personnel

Organizational Chart

Insert an organizational chart for your entire team

Contact Information

Please populate the following table with contact information for each team member. Please provide general area of expertise each will provide (e.g., microfluidics). In the last column, list tasks or otherwise briefly describe each individual's involvement in the effort.

Prime Team Members and Contact Information: [Institution]

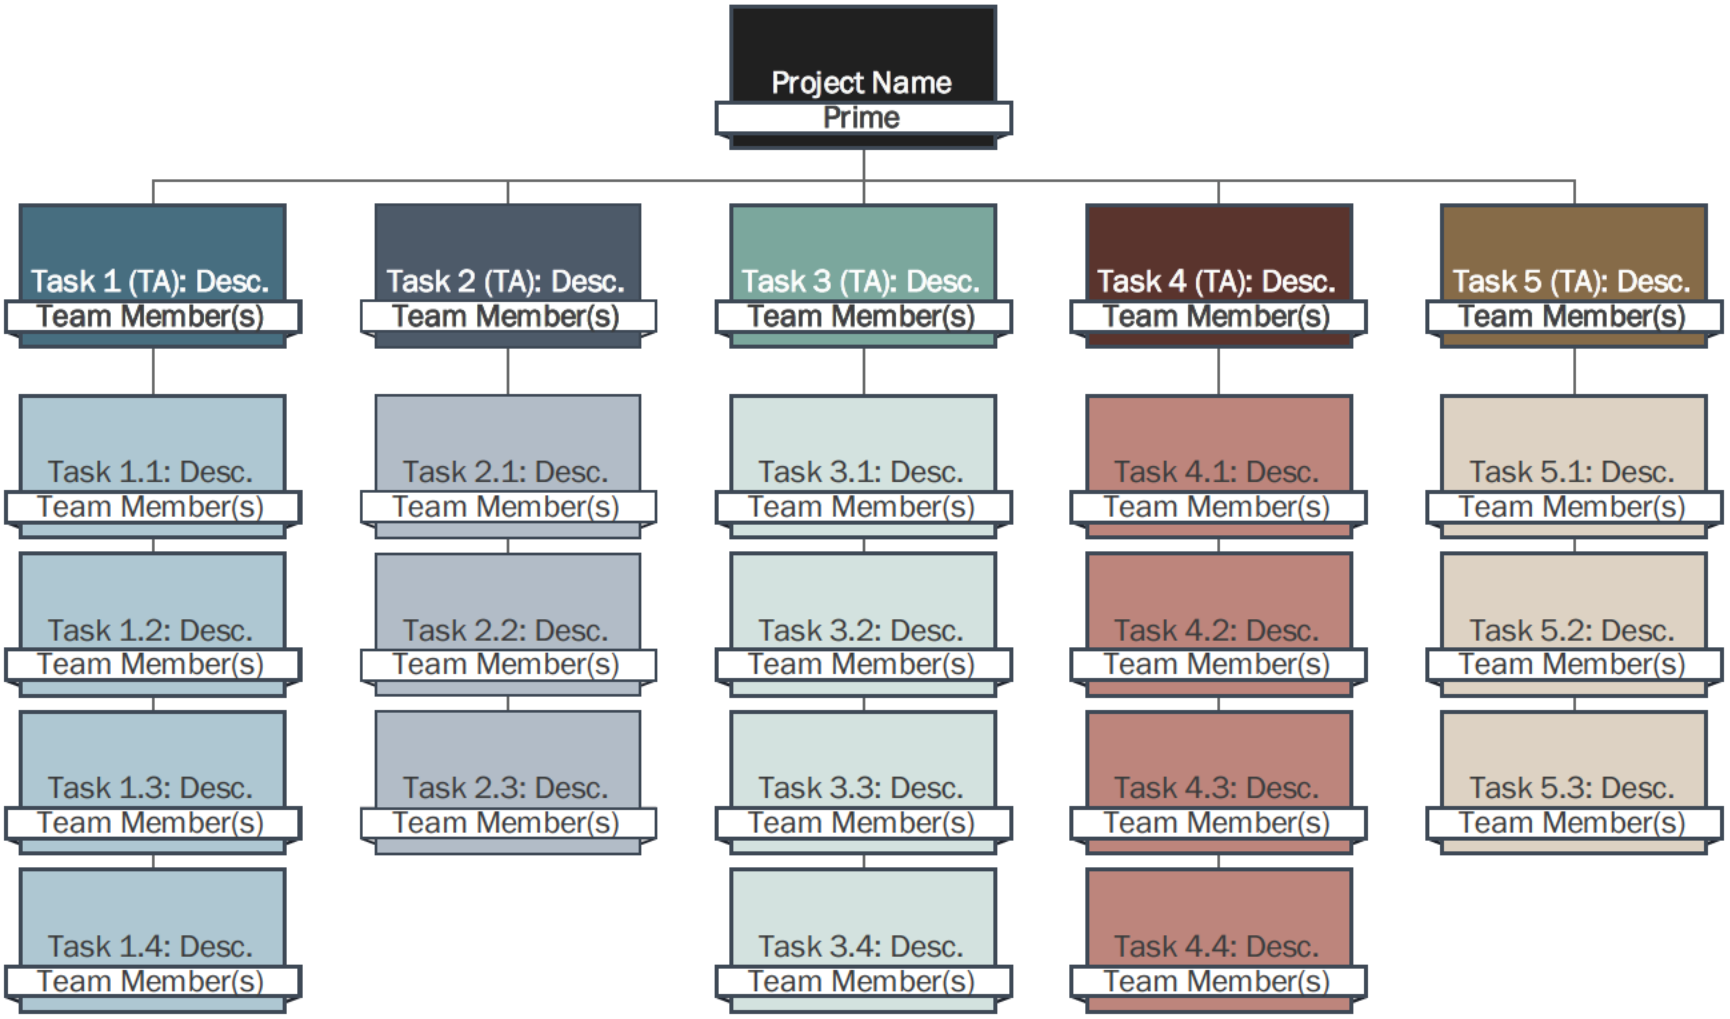
Role	Full name	Phone and email	Areas of Involvement
PI		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Subcontract Team Members and Contact Information: [Institution]

Role	Full name	Phone and email	Areas of Involvement
PI (expertise)		(888) 888-8888 XXX@univ.edu	
Co-PI (expertise)		(888) 888-8888 XXX@univ.edu	
Postdoc (expertise)		(888) 888-8888 XXX@univ.edu	

Work Breakdown Structure

Provide breakdown of tasking and assigned team members as per the template shown below



Monthly Financial Report Template

LINK TO TEMPLATE (click here)

Please use this template to provide monthly financial updates to the PREEMPT team. As you input your data, the graph will automatically update. ***Please keep past reports in this file and create a new tab each month. We want to see all reports in the same file. Title tabs "Phase-Month-Year, " e.g., "Base - January - 2015"***

LINK TO EXAMPLE (click here)

An example of a completed template is also provided. The example graph illustrates a scenario where the performer is under spending. It is designed to show how this template will make it easy for INTERCEPT performers to clearly communicate the status of their effort to DARPA so that both can plan for and initiate contractual actions quickly and effectively.

Spend Plan Data	
Period of Performance	The financial report will only cover the current phase (e.g., Base, Option 1, etc.). Use a format similar to "Sep-2013," not "Month 6." In order to plan for continuing resolution requests, DARPA may reach out to you separately to request your projected spend rate for future phases.
Phase Total	Total for current phase *(Example Graph - total is $1,000,000)* .
Funds Received	Funds awarded to date; most efforts are funded incrementally *(Example Graph - this effort received an increment for $500,000 in Oct-2012 to exercise the base, and received the remainder of their base period funding in Mar-2013 (remaining $500,000))* .
Spend Plan	Projected Expenditures must cover the entire phase.
Actual Expenditures (est.)	Actual Expenditures should not be solely based off of invoices you have submitted or received to date. Instead, it should be an accurate (to the extent that is possible) account of the expenses you have actually incurred to date. For example, if a subcontractor has incurred but hasn't invoiced $100,000 worth of work, include the $100,000 in your actual expenditures. Or a large amount of equipment valued at $50,000 that hasn't yet been invoiced should also be factored in to the actual expenditures.
Invoiced to Date	Report the invoices you have submitted to date *(Example Graph - the scenario used in the example graph submits invoices quarterly)* .
Issues/Updates Summary (if applicable)	
Use this section as an opportunity to bring issues, concerns, or updates to the attention of DARPA. For example, you can summarize reasons for over/under-spending, potential no-cost extension requests, invoicing problems, etc.	

***Amounts for Spend Plan, Actual expenditures, Invoiced to Date are cumulative.

Issues/Updates Summary (if applicable)
We anticipate that we will need to request a four-month no cost extension (NCE). The NCE is necessary due to delays we experienced while getting Subcontractor #1 under contract. Although our effort's period of performance began in October 2012, the subcontract was finalized and fully-executed in February 2013, which resulted in a four-month delay from the intended start date. Subcontractor #1 is conducting a 12-month study, and cannot speed up their experiments. We would, however, like to begin work on Option 1. We intend to perform these tasks in parallel to the extended Base Period tasks (which are primarily performed by Subcontractor #1).

REPORT OF INVENTIONS AND SUBCONTRACTS

(Pursuant to "Patent Rights" Contract Clause) (See Instructions on back)

Form Approved
OMB No. 9000-0095
Expires Oct 31, 2004

PLEASE DO NOT RETURN YOUR COMPLETED FORM TO THIS ADDRESS. RETURN COMPLETED FORM TO THE CONTRACTING OFFICER.

1.a. NAME OF CONTRACTOR/SUBCONTRACTOR	c. CONTRACT NUMBER	2.a. NAME OF GOVERNMENT PRIME CONTRACTOR	c. CONTRACT NUMBER	3. TYPE OF REPORT *(X one)*
				a. INTERIM ☐ b. FINAL ☐
b. ADDRESS *(Include ZIP Code)*	d. AWARD DATE *(YYYYMMDD)*	b. ADDRESS *(Include ZIP Code)*	d. AWARD DATE *(YYYYMMDD)*	4. REPORTING PERIOD *(YYYYMMDD)*
				a. FROM
				b. TO

SECTION I - SUBJECT INVENTIONS

5. "SUBJECT INVENTIONS" REQUIRED TO BE REPORTED BY CONTRACTOR/SUBCONTRACTOR *(If "None," so state)*

NAME(S) OF INVENTOR(S) *(Last, First, Middle Initial)* a.	TITLE OF INVENTION(S) b.	DISCLOSURE NUMBER, PATENT APPLICATION SERIAL NUMBER OR PATENT NUMBER c.	ELECTION TO FILE PATENT APPLICATIONS *(X)* d.				CONFIRMATORY INSTRUMENT OR ASSIGNMENT FORWARDED TO CONTRACTING OFFICER *(X)* e.

f. EMPLOYER OF INVENTOR(S) NOT EMPLOYED BY CONTRACTOR/SUBCONTRACTOR		g. ELECTED FOREIGN COUNTRIES IN WHICH A PATENT APPLICATION WILL BE FILED	
(1) (a) NAME OF INVENTOR *(Last, First, Middle Initial)*	(2) (a) NAME OF INVENTOR *(Last, First, Middle Initial)*	(1) TITLE OF INVENTION	(2) FOREIGN COUNTRIES OF PATENT APPLICATION
(b) NAME OF EMPLOYER	(b) NAME OF EMPLOYER		
(c) ADDRESS OF EMPLOYER *(Include ZIP Code)*	(c) ADDRESS OF EMPLOYER *(Include ZIP Code)*		

SECTION II - SUBCONTRACTS *(Containing a "Patent Rights" clause)*

6. SUBCONTRACTS AWARDED BY CONTRACTOR/SUBCONTRACTOR *(If "None," so state)*

NAME OF SUBCONTRACTOR(S) a.	ADDRESS *(Include ZIP Code)* b.	SUBCONTRACT NUMBER(S) c.	FAR "PATENT RIGHTS" d.		DESCRIPTION OF WORK TO BE PERFORMED UNDER SUBCONTRACT(S) e.	SUBCONTRACT DATES *(YYYYMMDD)* f.	
			(1) CLAUSE NUMBER	(2) DATE *(YYYYMM)*		(1) AWARD	(2) ESTIMATED COMPLETION

SECTION III - CERTIFICATION

7. CERTIFICATION OF REPORT BY CONTRACTOR/SUBCONTRACTOR *(Not required if: (X as appropriate))* ☐ **SMALL BUSINESS or** ☐ **NONPROFIT ORGANIZATION**

I certify that the reporting party has procedures for prompt identification and timely disclosure of "Subject Inventions," that such procedures have been followed and that all "Subject Inventions" have been reported.

a. NAME OF AUTHORIZED CONTRACTOR/SUBCONTRACTOR OFFICIAL *(Last, First, Middle Initial)*	b. TITLE	c. SIGNATURE	d. DATE SIGNED

DD FORM 882 INSTRUCTIONS

GENERAL

This form is for use in submitting INTERIM and FINAL invention reports to the Contracting Officer and for use in reporting the award of subcontracts containing a "Patent Rights" clause. If the form does not afford sufficient space, multiple forms may be used or plain sheets of paper with proper identification of information by item number may be attached.

An INTERIM report is due at least every 12 months from the date of contract award and shall include (a) a listing of "Subject Inventions" during the reporting period, (b) a certification of compliance with required invention identification and disclosure procedures together with a certification of reporting of all "Subject Inventions," and (c) any required information not previously reported on subcontracts containing a "Patent Rights" clause.

A FINAL report is due within 6 months if contractor is a small business firm or domestic nonprofit organization and within 3 months for all others after completion of the contract work and shall include (a) a listing of all "Subject Inventions" required by the contract to be reported, and (b) any required information not previously reported on subcontracts awarded during the course of or under the contract and containing a "Patent Rights" clause.

While the form may be used for simultaneously reporting inventions and subcontracts, it may also be used for reporting, promptly after award, subcontracts containing a "Patent Rights" clause.

Dates shall be entered where indicated in certain items on this form and shall be entered in six or eight digit numbers in the order of year and month (YYYYMM) or year, month and day (YYYYMMDD). Example: April 1999 should be entered as 199904 and April 15, 1999 should be entered as 19990415.

1.a. Self-explanatory.

1.b. Self-explanatory.

1.c. If "same" as Item 2.c., so state.

1.d. Self-explanatory.

2.a. If "same" as Item 1.a., so state.

2.b. Self-explanatory.

2.c. Procurement Instrument Identification (PII) number of contract (DFARS 204.7003).

2.d. through 5.e. Self-explanatory.

5.f. The name and address of the employer of each inventor not employed by the contractor or subcontractor is needed because the Government's rights in a reported invention may not be determined solely by the terms of the "Patent Rights" clause in the contract.

Example 1: If an invention is made by a Government employee assigned to work with a contractor, the Government rights in such an invention will be determined under Executive Order 10096.

Example 2: If an invention is made under a contract by joint inventors and one of the inventors is a Government employee, the Government's rights in such an inventor's interest in the invention will also be determined under Executive Order 10096, except where the contractor is a small business or nonprofit organization, in which case the provisions of 35 U.S.C. 202(e) will apply.

5.g.(1) Self-explanatory.

5.g.(2) Self-explanatory with the exception that the contractor or subcontractor shall indicate, if known at the time of this report, whether applications will be filed under either the Patent Cooperation Treaty (PCT) or the European Patent Convention (EPC). If such is known, the letters PCT or EPC shall be entered after each listed country.

6.a. Self-explanatory.

6.b. Self-explanatory.

6.c. Self-explanatory.

6.d. Patent Rights Clauses are located in FAR 52.227.

6.e. Self-explanatory.

6.f. Self-explanatory.

7. Certification not required by small business firms and domestic nonprofit organizations.

7.a. through 7.d. Self-explanatory.

SUBAWARD EXPENSE BUDGET

COST REIMBURSABLE EXPENSES - NO PAYMENTS IN ADVANCE

	Amount
Salaries	10,058.00
Benefits	2,877.00
Sub Awards	0.00
Contracted Services	0.00

Repair and Maint	0.00
Awards	0.00
Participant Support	0.00
Capital Equipment	0.00
Major Renovations	0.00
Facilities and Admin	7,504.00
TOTAL	**21,935.00**

Facilities and Admin (IDC) Basis: MTDC less equip, sub, part supp,awa Rate: 52% Base Amount: 14,431.00

This subaward is being issued to allow work to commence, however, no work with animals shall be authorized until IACUC/ACURO approvals are obtained. Any work with animals that occurs prior to such approval will not be reimbursed by the Pass-Through entity. Subrecipient agrees to provide documentation to Pass-Through entity of all necessary reviews and approvals prior to conducting any animal-related work.

IDENTIFY HOST IMMUNE SIGNATURES

Task 11.04 Lab: identify host immune and stress signatures in wild bats and in a captive feeding trial. CSU will provide advice on how to measure bat immune signatures.

Milestones
Immunology on samples from Australia (MSU):
• Provide advice on tests on bats from Australia (6mths)

Immunology on samples from Ghana (Cambridge):
• Provide advice on tests on bats from Australia (24 mths).

Task 11.08, Lab: amplification and transmission dynamics of quasispecies *in vitro* and *in vivo*. RML, with help from CSU, will undertake in vivo experiments to measure phenotypes of henipavirus strains.

Milestones
• Provide advice on infection experiments (24mths)
• Design experiments and develop IACUC protocols and submit paperwork for ACURO approval (24mths)

DEMONSTRATE PROOF OF CONCEPT, FEASIBILITY, AND SCALABILITY OF CHAD/VSV VACCINATION

Task 22.02, Proof-of-concept demonstration of ChAd/VSV vaccination feasibility and scalability of ChAd/VSV vaccination in bats. RML will develop and test a scalable vectored vaccine for target henipaviruses in bats. RML, with help from Cambridge, will assess the feasibility and scalability of the vaccine in bats.

Milestones
- Provide advice on vaccine development (24mths)

Invoices must meet the requirements of the Agreement Terms and Conditions.

1) Reference the MSU Subaward ID **G228-19-W7329** on all invoices.
2) Include current and cumulative costs by budget category (including cost sharing if required) on all invoices.
3) Include period covered by the invoice.
4) Invoices must be signed, dated and certified as to truth and accuracy. Invoices or vouchers requesting payment will include a certification, signed by an authorized official, which reads as follows: "By signing this report, I certify to the best of my knowledge and belief that the report is true, complete, and accurate, and the expenditures, disbursements and cash receipts are for the purposes and objectives set forth in the terms and conditions of the Federal award. I am aware that any false, fictitious, or fraudulent information, or the omission of any material fact, may subject me to criminal, civil or administrative penalties for fraud, false statements, false claims or otherwise. (U.S. Code Title 18, Section 1001 and Title 31, Sections 3729–3730 and 3801–3812)."

Hello,

Sorry for the delay. The partially executed amendment is attached. We look forward to receiving the fully executed copy.

Thank you,
Julie

Julie Harvey
Research Administrator

Please note: the Office of Sponsored Programs will be closed during the CSU holiday shutdown (December 23, 2019 through December 29, 2019). If forms or correspondence are received during that time, there will be a delay in our reviews or responses until our return to the office on December 30, 2019 at the earliest.

Thanks for the information.

I will leave Julie in as Auth Official and replace you as Admin Contact with Ashley. Is her info the same as yours, or does she have a different phone and/or address? Once I have that info I will update and resend the amendment.

Per the clarifications noted below, please find a revised Amendment 1 for MSU Subaward G228-19-W7329.

If the agreement terms and conditions meet your approval, please have it signed (manual or electronic accepted) by your institution's authorized representative and return at your earliest convenience. Upon final execution, a scanned fully executed copy will be returned for your file.

Return signed documents **by email to**: subawards@montana.edu

I trust that the sub-award is in agreement with your understanding; however, if there is need for a change, please contact subawards@montana.edu or call as soon as possible. Do not make changes in the document as prepared until a mutual agreement has been reached.

Sincerely,
Jennifer

Subject: RE: Memo to: Colorado State University G228-19-W7329 Amendment 1 draft

Hi, Jennifer,

Upon further review of our documents and after talking with Susan Rogers, it looks like we still need the remaining Year 1 budget for the animal work as well as the animal work for the first part of Year 2 now that we have received our ACURO approval.

Also, Susan had received the attached Subaward Modification Request, is this an amendment that is still in process? If so, the $12,488.45 from the attached Amendment 1 would need to be removed from the total of $56,515.

	Remainder Yr 1	Yr 2 (60%)	Total
Schountz, Tony		$ 7,491	$ 7,491
Eckley, Miles	$ 5,451		$ 5,451
Schountz fringe		$ 2,142	$ 2,142
Eckley fringe	$ 1,564		$ 1,564
Materials	$ 660		$ 660
Bat Per Diem	$ 8,702	$ 5,880	$ 14,582
Bat Overnight Shipping	$ 1,000		$ 1,000
Hamilton Trip	$ 2,794		$ 2,794
Bozeman		$ 1,496	$ 1,496
Direct Total	**$ 20,172**	**$ 17,009**	**$ 37,181**
F&A	$ 10,489	$ 8,845	$ 19,334
Total	**$ 30,661**	**$ 25,854**	**$ 56,515**

Thanks,

Julie Harvey

Hello Julie,
We have received 60% of Year 2 funds. Once we receive the remaining, the subaward will be modified to the full Year 2 amount.
Thank you,
Jen
